A

Abattoirs (see also Chicago stockyards)
Abbe, Prof., death of, 395
Abdomen, contusion of the (Mr. A. Webb Jones), 569
Abdomen, Surgical Diseases of the (Dr. R. Douglas) (review), 435
Abdomen, thorax and, shifting dulness in the, 561
Abdominal cyst, chylous, 557
Abdominal hydrocele (Lt.-Col. J. Lewtas, I.M.S.), 489
Abdominal hysterectomies for fibro-myomata, 502
Abdominal hysterectomies, 100 consecutive (Mr. J. Bland Sutton), 1406
Abdominal incisions (Mr. C. S. Wallace), 792
Abdominal injuries in children (Mr. H. Burrows), 424
Abdominal muscles, absence of the, 1201
Abdominal operations, administration of anæsthetics in, 164
Abdominal pain and pyrexia, 1191
Abdominal pregnancy, 1603
Abdominal sections for abnormal pregnancies, &c. (Mr. J. Scott Riddell), 1184
Abdominal tumour, 1000
Abdominal wall, laceration of the, the result of bear bite (Mr. V. S. Umachigi), 494
Abdominal wounds, 1608
Abdomino-perineal excision of the rectum (Mr. R. W. Murray), 1193
Aberavon, workmen's houses at, 1384
Abercrombie, Dr. P. H., epithelioma of the larynx, 1551; sarcoma of the frontal sinus, 1551
Aberdeen Royal Infirmary, 395; Sick Children's Hospital, 676; Morningfield Hospital, 1754
Aberdeen, typhus fever in, 198, 532; health of, 474, 1334, 1453
Aberdeen University, extension at the, 826; graduation, 1040
Aberdeen University Club, London, 1217
Aberdeen University Medical Society, 1545
Abernethy, Mr., lectures by, in the year 1827, 245, 816, 1293
Aberystwith, health of, 825
Aberystwith Infirmary and Cardiganshire General Hospital, 395
Abortion during an attack of enteric fever, 289
Abortionist, a twice-convicted, 876
Abrahams, Dr Bertram L., arthritis deformans and its allies, 717, 718
Abscess, cerebral, encysted (Dr. Peter Paterson), 214
Abscess, extradural, following mastoid disease, 93
Abscess of the lung, 1719
Abscess, pericolic, 835
Abscess, subphrenic, 289, 337
Abuse, hospital, 590, 606, 817, 1167, 1366
Academische Auskunftsstelle (see Information Bureau)
Academy of Medicine and Surgery, Russian, 249
Acarus of scabies, history of the discovery of the, 49, 510
Accident, anthrax an, under the Workmen's Compensation Act, 1093; is lead poisoning an, 1383
Accidents (Mines and Factories) Bill, 937, 947, 1088
Accidents connected with motor-cars, 1279; street and road, 1653
Accidents, fees for attending, 1462
Accidents, railway, in the United States, 1149
Accidents, slight, but susceptible of fatal developments, 461
Accrington, small pox in, 1034, 1600; high death rate at, 1690; plunge bath, 1461
Acetone bodies, 1056
Acetonuria in children, 872
Achard, M. C., pulmonary fistula, 1284
Acholia, 1138
Achondroplasia, 720
Acromegaly, 165, 293, 1137
Act (see also Anatomy Bill, Companies, Diseases of animals, Midwives, vaccination, Workmen's compensation, &c.)
Actinomycosis, 932, 993, 1003
Action at law against a medical man for breach of promise of marriage, 194; in regard to the sale of a medical practice, 455; against the Clevedon Urban District Council, 607; against a medical man (charge of adultery), 728; *for slander*, 762; *for slander and dismissal*, 1554; in regard to treatment, 892, 1755; for manslaughter, 894; *for alleged negligence and breach of duty*, 1660; by a medical man to recover compensation for an accident, 1039; *to recover fees*, 1732
Adams, Dr. C. E., carcinoma of adrenal, 930
Adamson, Dr. H. G., ringworm, 1715
Addenbrooke, Dr. Bertram, various cases, 364; pulmonary tuberculosis, 974
Addinsell, Dr. A. W., premenstrual pregnancy, 791
Addison's disease, 296, 498, 1074
Addison Temperance Reader (Mr. W. Finnemore) (*review*), 96
Aden, plague at, 261, 1033, 1613
Adenoids and enlarged tonsils, technique of the operation for (Dr. F. C. Carlé), 1265
Adenoma of the gall bladder, 999
Adenomyoma, diffuse, 1407
Adiposis dolorosa, 648
Admiralty appointment, 970
Adolescent insanity, prognosis of (Dr. T. S. Clouston), 386
Adolescents, premature dementia of, 312
Adrenal, carcinoma of, 930, 1499
Adrenalin, 97, 241
Adrenalin extract and saline fluid, intravenous *injection of*, 92
Adrenalin, injections of, alteration of the arteries produced by, 1222; in asphyxia, 1547
Adrenalin, use of, by immigrants, to conceal trachoma, 62
Adulteration, 511
Adulteration of brandy, 242; of milk, 453, 535; *of whisky*, 464; of wine, &c., 892; of beer, 1024; *of butter*, 1041
Advertisement (see also Maladvertisement)
Advertisement, a medical man's, 66; unfortunate, 1164
Advertisements, picture post-card, 269
Advertisements quoting What THE LANCET has not said, 470
Advertising and canvassing to procure patients, 1514
Advertising by dentists, 1507
Advertising by quacks, 101, 376, 878, 1309
Aerating machine for milk and other foods, 541
Aerial dissemination of small pox, 320, 447, 948, 1271, 1341, 1381, 1406, 1520, 1529, 16

Aerial transmission of infection, 320
Æsculapius (see also Asklepios)
Afghanistan, Amir of, and English medical officers, 252, 894
Africa (see South Africa, West Africa, Natal Transvaal, Sahara, Lake Nyasa, &c.)
Africa, phthisis in, 13, 14
African natives, surgical cases in (Mr. A. R. Young), 991
After Care Association, 447, 513
"After damp" (see also Fainting)
Agar, Mr. Samuel Hollingsworth, obituary, 636
Age, determination of, in the living, 951
Age incidence of cancer, 1031
Age limit for the honorary staff at Edinburgh Royal Infirmary, 194
Age, old, 590
Agencies, private, safeguarding of the public by, 308
Agglutometer, typhoid, 1505
Agriculture (see also Board of; Economic Biologists)
Air (see also Mine air)
Air, amounts of neon, helion, and hydrogen in the, 1285
Air and clothes, extension of infectious diseases by, 275
Air borne infection from small-pox hospitals, 1589 (see also Aerial)
Air deodoriser, stellite, 507
Air, fresh, and the burglar, 1445
"Air hunger" and yawning, 174
Air, pollution of, by saliva, 106
"Airlight," the, 1243
Albany, H R H the Duchess of, 1470
Albumin, action of a new form of dialysed iron on, 1370
Albumin pocket test case, 334
Albumosuria, myelopathic, 207, 211
Alcohol (see also Inebriates, Intemperance, Licensing, Temperance)
Alcohol a food ? 174
Alcohol, changes in the viscosity of the blood produced by, 98, as a protoplasmic poison, 125, and insanity, 244 250, 631, 674, 1757; action of, on the heart, 432, and tuberculosis, [illegible] use of, [illegible] ns, 762, [illegible] e treat- [illegible] indus trial, 1077, and physical deterioration, 1038; medical men and the use of, 1306, and heredity, 1675
Alcohol, wood, poisoning by, 196
Alcoholic Poisoning and Degeneration (Prof. G. Bunge) (review), 1346
Alcoholism, chronic (Dr. C. F. Tucker), 1244
Alexander, Dr D. A, *mosquito curtains and malaria*, 1043
Alexander, Dr. James, obituary, 1039
Alexander, Dr. William, gynæcology, 431; myoma, 719, hydrochloric acid, 1120
Alexandra Hospital, Montreal, 127
Algeria, malaria in, 1618
Alien and immigrant London in 1781, 1363
Alien lunatics and imbeciles, pauper, 832
Aliens, trachoma among, 62, 1525
Alimentary value of sugar in tuberculosis, 1150
Alkaline water (see also Kalitzer)
Allan, Dr. F. J., phthisis, 1424
Allan, Dr Percy, registration of nurses, 1473
Allbutt, Prof. T Clifford, apoplexy, 181; blood pressure in man, 376, influenza, 734, 1270, visit of *British physicians and surgeons to* Paris, 1350 1351
Allchin, Dr W H, nutrition and malnutrition, 1111, 1180, 1250, 1319, 1519
Allegheny and Pittsburg, small pox and slums at, 527
Allen, Mr. A. Taylor, New Streets (review), 866
Allen, Mr. J. Fenwick, St. Helen's Hospital, 1554
Allen, van, Dr. H. W., dangers of the x rays, 945
All malt stout (Grouse brand), 368
Allport, Mr. Douglas, housing, 370
Alms-giving, physical infirmity and, 103
Alopecia universalis, 855
Alphozone, 367
Alveolar abscess, 928
Alverstone, Lord, Centenary of the Royal Medical and Chirurgical Society, 1436
"Amass," 867, 1030
Amalgamation of McGill Medical Faculty and Bishop's Medical College, 955
Amat, M, grafts from the lining membrane of egg shell, 1257
Amaurotic family idiocy, 537
Ambidexterity from the point of view of the physician, 622, in art, 830; from the surgeon's point of view, 1103
Ambidextral Culture Society, 537
Amblyopia, tobacco, 424, 831
Ambulance (see also Civil Ambulance, volunteer ambulance, street ambulance)
Ambulance service in *Bristol*, 124
Ambulance Tablets (Dr. S. Partridge), (review), 31
Ambulance, the field, 1226
Ambulance *work and general practitioners*, 363
Ambulances, street, 66, 399
Ambush II. (the famous race horse), 675, 963
Amenorrhœa and menorrhagia, 1136
America or American (see also New York, correspondence from United States, visit of THE LANCET Special Sanitary Commissioner, Pan American
America, medical practitioners in, law relating to, 108; obstetric duties of the army surgeon in, 239
America, South (see also British Guiana)
American anatomists, conference of, 1238
American Association for the Advancement of Science, 128
American editors, some, 470
American Medical Association, 393, 829, 965
American Mosquito Extermination Society, 200, 685
American nurses in Japan, 1028
*American Ophthalmological Society, Trans*actions of the (review), 1273
American Physicians, Association of, Trans [illegible] *464, 679* [illegible] Canada, Limited, 470
Amethyst tinted window, 512, 1378
Amir of Afghanistan and English medical officers, 252, 894
Ammonia, bath and home, 1656
Ammonia, fluid, poisoning *by (Dr. H. Savory)*, 1572
Amœbic dysentery, 104
Ampthill (see Lady Ampthill)
Amputation of the leg, 558, 560, 1331
Amputation, spontaneous, gangrene with Capt E. O Thurston, I M S), 1331
Amputation under spinal anæsthesia with eucaine, 1683
Amputations, calcium iodate in the treatment of, 144
Amyl, nitrite of, in deep seated hæmorrhage, 800, in [illegible] 1036
Anæmia, [illegible] splenic, 503, 571, [illegible] 81
Anaerobic micro organisms, 550
Anæsthesia (see also Nitrous oxide gas)
Anæsthesia, 950
Anæsthesia at the Hotel Dieu, 1448
Anæsthesia, chloroform, 117, 387, 1037
Anæsthesia, chloroform complicated by a fit (Mr. A H Brewer), 187
Anæsthesia, chloroform, surgical shock after, 1237
Anæsthesia produced by stovain, 828, 1456; by spinal injections, 1456 1683
Anæsthetic, choice of an, 201, 270; a new, 589
Anæsthetic, scopolamine as an, 1037
Anæsthetic mixtures, 1074
[illegible] sterilisable inhaler for [illegible] ts, 269, 525
Anæsthetics, administration of, by dentists, 541, 1101, by unqualified dentists, 1392
Anæsthetics, administration of, in abdominal operations, 164
Anæsthetics, effects of, 778
Anæsthetics, inhalers for administering, 33, *302, apparatus for*, 1755
Anæsthetisation of children, 230
Anæsthetists, Society of, 756
Analgesia produced by stovain, 828, 1456
Analysis of Irish butter, 971
Analysis, Qualitative Chemical (Prof. A. Liversidge) (review), 1654
Analysis, Quantitative Chemical (Dr. J C Olsen) (review), 575
Analysis of rain and the public health, 1593
Analysts' Certificates under the Sale of Food and Drugs Acts, 453
Analyst's report, Birmingham City, 962

ANALYTICAL RECORDS FROM THE LANCET LABORATORY.—Clinical thermometers (half-minute observation), Crémant du Roi (Saumur Veuve Amiot); Cheltine malted milk cocoa, Brandies (A. L Boiteau and Co), Vinciglista Italian wine, Maltoff, Argex fluid beef, 32, 33—Alphozone, Pine tar soap, Kalitzer sparkling water, Offley's "Duke" very old port, Robb's soluble milk foods; Kresopen; All malt stout (Grouse brand), Cape Hermitage wine; Cailler's Swiss milk chocolate, 367, 368—Sodium perborate (Wellcome brand), "Record" old Scotch whisky; Choco um; Calox; Dietetic [illegible] bars, Gilmour's oatmeal stout (Quaker brand), Sultana bread, Bitter beer, 574, 575—Cerafine petroleum jelly, Scotch whiskies, Malt co, Marsala wine (Old Particular brand), 867—Sterilisol, Gluten bread, Spanish brandy, [illegible] hardt), and (2) [illegible] la soap, [illegible] le and are[illegible], [illegible] Nursing on [illegible] jams, 11[illegible] (1) "Wellcome' brand chloroform, and (2) Borofax; Vinolia white coal tar soap, Infants' food; Chinosol compressed tablets, Diastase setterie, Vichy water and other mineral waters, Toffee; Cheltenham natural aperient water, Gold Reef clotted cream, Three Star Swiss dry milk, 1348, 134[illegible] Ophthalmic capsules; "Artox" wholemeal flour and bread; Therapeutic yeast, Robb's milk food; Garcon coffee; Hansen's junket tablets · (1) Swedish fish balls, and (2) Bath and home ammonia; Skipper sardines; Manhu diabetic foods, 1655, 1656

Analytical Special Commission of THE LANCET on Brandy, 513
Anastomosis, intestinal, soluble button for (Dr. P Paterson), 858
Anastomosis, nerve, 1282
Anatomical Museum, Liverpool University, the King's gift to the, 675, 963
Anatomical peculiarities of a gall bladder and an appendix (Dr. F. Lemon), 1265, 1283
Anatomical specimens, essential oil of mustard as a *preservative for, 893*
Anatomie des Membres (Dr. Ch. Dubreuil) (review), 506
Anatomie des Menschen (Dr. Med. J. Sobotta) (review), 30
Anatomists, American, conference of, 1236
Anatomy Acts, operation of the, *1466*
Anatomy and Physiology, Journal of (review), 96, 1141
Anatomy and Physiology, Elements of, Especially Adapted for Nurses (Mr. W. B Secretan) (review), 650
Anatomy (see also Morphology and Anthropology)
Anatomy, Applied (Dr. Edward H. Taylor) (review), 298
Anatomy, comparative, mammalian, 232
Anatomy, Edinburgh Stereoscopic Atlas of (review), 1580
Anatomy, Human, Atlas of (Prof. Carl Toldt) (review), 252
Anatomy, Human, Atlas of (Prof. Spalteholz) (review), 1429
Anatomy of drunkenness, 1223
Anatomy of the Brain (Dr. J. F. Burkholder) (review), 31
Anatomy, Surface (Dr. T. Gillman Moorhead) (review), 1430
Ancoats hospital, 461
Andalusia (see Land of the Blessed Virgin)
Anderlicht (near *Brussels*) slaughter houses, 259
Anderson, Dr J., treatment by light, 231
Anderson, Dr. John, interventricular septum, 166
Anderson, Dr. J. Ford, influenza, 1270
Anderson, Dr. J Wallace, Home Nursing and Hygiene (review), 234
Anderson, Dr Kenneth, typhoid fever, 228
Anderson, Miss A M, health of girls, 93
Anderson, Prof McCall, tuberculin, 1526
Andrews, Dr H Russell, uterine fibroid, 1001; ruptured interstitial pregnancy, 1648
Andriezen, Dr W. L, functional insanity, 90
Anencephalic fœtus, 32
Aneurysm, gelatin in the treatment of, 1169
Aneurysm of the aorta, 428, 1523, simulating Pott's disease, 1370, simulating dyspepsia, 1718, of the innominate artery, 799, 1467, intrathoracic, 1000, 1201, of the axillary artery, 1130 1755, popliteal, spontaneous gangrene of the leg in, 1326
Aneurysm, Russian wounded operated on for, 392
Aneurysm, x rays and, 1426
Aneurysms in warfare, 257, 332
Angina, Ludwig's, 1719
Angina pectoris, 1216
Angina pectoris and Pseud-angina (Sir W. H *Broadbent*), 1003, 1339
Angine à spirilles et bacilles fusiformes (angine de Vincent), (Prof H. Vincent), 1260, 1261
Angio-neurotic œdema, hereditary, 43, of the intestine, 1083
Angora ewe, *morbid growth from an*, 1421
Aniline violet ink, poisoning by, 533
Anim[illegible] (see also Pasteur Institute)
Animals (see also Cattle, hogs, slaughtering pens, ticks, anthrax, Diseases of Animals Act)
Animals and man, plague in, 1237, 1563
Animals, experiments on, 611, 831, 832, [illegible] 1133, 1221, 1551, 1753
Animals, [illegible], 1713
Animals, [illegible] diseases of, [illegible]
Ankle [illegible], tuberculous affections of the, 139
Ankylosis and contracture at the knee (Mr T. H Openshaw), 1[illegible]4, 173
Ankylosis, bilateral, of the jaw, 1[illegible], of hip-

joints, 1135; *fibrous, of the shoulder-joint*, 1136; semi-resection of the elbow-joint for, 1237
Ankylostoma, 255, 397, 533, 1681
Ankylostomiasis, 859, 864
Annali di Medicina Navale, 1094
Annual meetings (see Hospitals and societies, annual meetings of)
Annual, The Medical (review), 1430
Anopheles Mosquitoes of India (Capt. S. P. James and Capt. W. G. Liston) (review), 1345
Ante-natal injuries, 813, 877
Anthrax, 59, 309, 364, 605, 801, 802, 875, 1137, 1539
Anthrax an accident under the Workmen's Compensation Act, 1093
Anthrax in Great Britain, 591; in Nürnberg, 747
Anthrax treated with Prof. Sclavo's serum (Mr. J. Lionel *Stretton*), 292, 1420; *industrial* (Dr. T. M. Legge), 639, 765, 841
Anthropological Laboratory of the Anatomy School, Cambridge, Studies from the (Mr. W. L. H. Duckworth (review), 166
Anthropology (see also Morphology and Anthropology)
Anti-cancerous serum, 793, 955
Antidiphtheritic serum, local action of, 1699
Antidiphtheritic toxin, 629
Antidotes to nicotine, 1595
Antimony (see also Rubber, red)
Anti-nicotine tobacco, 132, 201
Anti-pneumococcus serum, pneumococcus endocarditis treated by (Dr. Horder and Dr. Scofield), 1333
Antiseptic (see also Carbonic acid gas)
Antiseptic action of bismuth salts, 432
Antiseptic properties of certain vapours, 1037
Antiseptic *v.* aseptic methods in plastic surgery, 562
Antiseptics (see also Kresophen)
Antistreptococcic sera, 926
Antistreptococcic serum, endo*carditis treated* by, 420; acute septicæmia treated with, 487; pyrexia following childbirth treated with, 1571
Antitetanic serum, 590
Antitetanic serum, tetanus treated by (Dr. R. A. Stoney), 1133
Antitoxin, diphtheria, 278, 1285, 1381
Antitoxin for the *treatment* of syphilis, 329
Antitoxin, tetanus, 1455
Antitoxins, 1204
Antituberculous dispensary, 673
Antituberculous serum, Marmorek's, 928
Antituberculous vaccination, 1145
Antityphoid Inoculation, report of the German Commission on, 1453
Antivaccinationists *in* the educated classes, 735
Antivenin, Calmette's, 353
Antivivisection speech by a Government official, 1547 (see also Animals)
Antrum of Highmore, empyema of the, 151
Anuria, calculous, 429
Aorta, aneurysm *of* the, 428, 1525; simulating Pott's disease, 1373
Aortic orifice, double stenosis of the (Dr. T. Shennan), 21
Aortic regurgitation with angina, 1216
Aortic stenosis, 295
Aortitis, acute (Sir W. H. Broadbent), 1401; (Dr. W. *Broad*bent), 1412
Apert, M. E., œdema of the glottis, 43
"Apex beat," the term, 499
Aphasia, after severe convulsions, 137; hereditary, 425; congenital, 1527
Apoplexy (Prof. T. Clifford Allbutt), 181
Apoplexy of the ovary, 231
Apothecaries' Hall of Ireland, examinations of the, 1452
Apothecaries *in* England and Ireland in the year 1827, 1157
Apothecaries' Society, London, pass lists, 129, 256, 537, 829, 1040, 1171, 1470; Gillson scholarships, 376; and midwives, 846; the title of the licentiates of the, 58, 119, 1146, 1229, 1310, 1442, 1468, 1584, 1609; St. Luke's window, 1339; *registration* of nurses, 1393; examinations, 1452; assistant examiner in surgery, 1515
Apparatus, continuous extension, in treating fractures of the leg, 603
Apparatus for fractured femur, 646
Appeals to charity, 1145, 1751
Appel, Miss E. L. C., M.B., feeling and emotion, 1722
Appendicectomy (see also Pre-appendicectomy)
Appendicectomy, 551
Appendicitis, 293, 401, 445, 459, 511, 548, 552, [illegible], 642, 647, 714, 795, 822, 932, 934, 1002, 1137, 1342, 1455
Appendicitis (Sir Frederick Treves), 509

Staphylococcus albus in peritonitis, 478
Staphylococcus pyogenes aureus, cyllin inhalant and the, 987
Staple, Mr J. D., peritonitis and purgative pills, 1577
Star Calendar for 1905 (review), 300
Starling, Dr. E H, proteids 717
Stasis, pressure (Dr H W. King), 959
State boards of health, 1682
State registration of nurses, 41, 610, 831, 969, 1104, 1390, 1392, 1551
Static machines, x rays from, 175
Statistical indications of a relation between erysipelas, puerperal fever, scarlet fever, and rheumatism, 295
Statistical study of medicine, 1406, 1657
Statistical tables of appendicitis, 590
Statistics (see also Vital statistics, Royal Statistical Society)
Statistics of the distribution of phthisis, 10, 78, 314, 376; of the medical profession in Italy, 34, in the United Kingdom, 102, 397, 593, of medical students in Austria, 1099, of Chicago and its stockyards, 50; of the population of Ireland, 60, military medical, 63, of the war in the Far East, 116, 384, 458, of the sexes in the United States, 127, of infectious diseases in Italy, 126, in Victoria, 196, in Toronto, 397; of cases of fracture of the skull, 177; of the Public Health and Marine Hospital Service of the United States, 196; of multiple gestation, 243; of diseases in London in 1903, 247; of London in 1781, 1358; of scarlet fever, 273, 276, 278; of plague in India, 324; of the death-rate of coloured people in the U.S A, 389, of appendicitis, 569, 590, 715; of gynæcological laparotomies, 570; health, of the Panama Canal, 1601
Stawell Hospital (Victoria, Australia), 197
Steamboats, the Thames, 1738
Steele-Perkins, Dr. George, hæmorrhoids, 1032
Stellite air deodoriser, 507
Stenosis, congenital, of the œsophagus (Dr. Whipham and Mr. Fagge), 22
Stenosis, double, of the aortic orifice (Dr. T. Shennan), 21
Stenosis, mitral "soft valve," 428
Stenosis of the ureter, 861
Stentor, the (one of the protozoa), 42
Stephenson, Mr. Sydney, strabismus, 324; tuberculosis of the lacrymal sac, 865, keratomalacia, 865; cribriform choroido retinitis, 1648
Stereoscopic Atlas of Anatomy, The Edinburgh (review), 1580
Sterilisation and pasteurisation of milk, 294
Sterilisation and preservation of foods by carbonic acid gas, 541
Sterilisation of catgut, 1150, 1448; of the surgeon's hands, 1425, 1448; of surgical instruments 1425
Sterilised milk, 265, 873 (see also Milk)
Sterilised milk depôts in Paris, 588
Sterilisol, 1075
Sterility (see also Azoospermia)
Sterules, brandy, 1583
Stethoscope, Laennec's, 1355, 1356
Stethoscope, use of the, 482
Stretton, Mr. J Lionel, wrist wound, 934; gall stones, 934, appendicitis, 934
Steven, Dr. J Lindsay, splenic anæmia, 503
Stevens, Dr. B. Crossfield, latent pneumothorax, 1124
Stevens, Dr. W. Mitchell, acute leukæmia, 153
Stevenson, Dr. Edgar, orbital exostosis, 430, 800
Stevenson, Robert Louis (Dr. A. H. Japp), (review), 437
Steward, Mr. F. J., hydronephrosis due to moveable kidney, 1069
Stewart, Dr. Purves, oculo motor paralysis of the eye, 434; cervical sympathetic paralysis, 434, narcolepsy and hysterical blindness, 571
Stewart, Miss Isla, Nursing (review), 31
Stewart, Mr. R C, alcohol, 1088
Stewart, Mr W. R H., suppuration of the eyelid, &c, 1420
Stieda Dr, fracture of the skull, 1537
Stigmata of degeneration, 426, 708
Stiles, Mr. Harold J, carcinoma, 645; chronic hydrocephalus, 1425; paralytic obstruction, 1425
Still, Dr. George F., hypertrophy of the pylorus in infants, 632
Still's type of chronic disease of the joints, 1424
Stimulins, 794
Stirling District Asylum report, 250
Stockyards of Chicago, 45, 49 120, 183, 258
Stoddart, Dr W. H. B, mental disorders 1651
Stoeckel, Dr Walter, Cystoskopie des Gynaekologen (review), 1006
Stoker, Sir Thurnley, cleft palate, 1500
Stokes Adams Disease, 1201
Stomach (See also vomiting)
Stomach, atonic dilatation of the, 1423
Stomach, cancer of the, after pylorectomy, 427
Stomach, diffuse hyperplasia of the, 574
Stomach, dilated and dropped, Recklinghausen's disease associated with 296
Stomach, perforated ulcer of the, 793
Stomach, subacute perforation of the, 1444
Stomach, ulcer of the, mercurial poisoning or? 1156
Stomach, ulceration of the, recrudescent, 1499
Stomatitis after the administration of mercury, 289
Stone, Dr. W. Gream, hereditary aphasia, 423
Stones, kidney, x ray diagnosis of, 432, 1632
Stoney, Dr. R. Atkinson, tetanus, 1134, tuberculous cæcum, 1499
Stoney, Miss Emily, M A, Bacteriology and Surgical Technic for Nurses (review), 1004
Stout, all malt (Grouse brand), 368, Gilmour's oatmeal (Quaker brand), 578
Stovain, 828, 1456, 1681
Stowers, Dr. J. H, mixed sclerodermia, 433
Strabane union dispensary district, 539
Strabismus, treatment of, 61, 254, 324
Strap, safety, for infants, 1044
Streams, purer, 1301
Street accidents, 1663
Street Ambulance Corps, Vienna, 1387
Street Ambulances, 66, 399
Street trading by children in Dublin, 463
Streets (see also New streets)
Streets, breaking up the, 1016, 1244, dangers of the, 1080
Streets, London, manners in the, 1012, 1108, 1174

LIST OF ILLUSTRATIONS.

COLOURED.

Two plates in colours illustrating the Cultivation of Trypanosoma out of the Leishman-Donovan Body upon the method of Captain L. Rogers, I.M.S., described by Dr. G. C. Chatterjee, 16

Full-page plate in colours illustrating Dr. Lane Joynt's paper on Pressure Stasis, 856

Seven figures, accompanying a lecture on Recurrent Effusion into the Knee-joint after Injury delivered by Sir William H. Bennett, K.C.V.O., 3, 4

Illustration of the Luys Separa[illegible] 'cal Lecture on a Simple Method of [illegible] the Urine secreted by each of the T [illegible] r. W. Bruce Clarke, 6

Three Diagrams illustrating the Etiological Differences between Congenital and Acquired Herniæ of Children, accompanying paper on the Pathology and Treatment of the Herniæ of Children and their Relation to Conditions in the Adult by Mr. R. Hamilton Russell, 7

Five Diagrams of Young Children showing the Disposition of the Limbs in Walking and Standing, accompanying paper on Child Study and the Treatment of Paralysis in Children by Dr. Alfred A. Mumford, 17, 18

Pulse Tracings accompanying paper on Diet in Chronic Diseases (Dr. John Haddon), 19, 20

Photoprint showing the Aorta Laid Open and a Fibrous Ring Below the Aortic Opening, accompanying notes on a case of Double Stenosis of the Aortic Orifice described by Dr. Theodore Shennan, 21

Photoprint of a drawing of the Œsophagus laid open from behind, showing the Position and Extent of the Stricture in a case of Congenital Stenosis of the Lower End of the Œsophagus (under the care of Dr. T. R. C. Whipham and Mr. C. H. Fagge), 24

Photoprint of a Male Child showing Mammary Enlargement and Abnormal Size of the external Genital Organs, illustrating a case of Precocious Lactation (under the care of Dr. Montagu Murray), 26

Two Photoprints of an Arab Patient's Head some days after admission to, and on leaving, the Omdurman Civil Hospital, illustrating a case of Sword Wound of the Head (under the care of Mr. E. S. Crispin), 26

Illustration of a New Form of Inhaler for administering all the ordinary anæsthetics, described by Mr. C. Hamilton Whiteford, 33

Illustration of a New Rectal Dilator and Diagram showing the various sizes of the same, described by Mr. P. Lockhart Mummery, 34

Drawing of a New Form of Vaginal Electrode devised by Dr. Sneguireff, 34

Photoprints [illegible] Commi [illegible] Special Sanitary insanit [illegible] the dark and hogs. [illegible] of cattle and 51, 52 [illegible] Packing Town, being removed, 121. Fig. 7, Bird's-eye view of the cattle pens [illegible] Fig. 6, Hides with cattle-run in the background, 183. Fig. 8, Main entrance to stockyards with inclined cattle-run, 183. Fig. 9, View over the dumping ground of the town refuse, 184

Blood Chart Before and After the Commencement of Radio-therapy, accompanying paper on the X Ray Treatment of Leukæmia by Dr. J. C. G. Ledingham and Dr. R. G. McKerron, 72

Illustration of an Aseptic Operation Table made of "Phosphor Bronze," with head- or leg-rest and an improved means for altering the plane of the table, and illustration of a Patent Corner of an Aseptic Dressing Table, 97

Illustration of an Intralaryngeal Syringe, described by Dr. Wyatt Wingrave, 97

Five Skiagrams illustrating a case of Osteomyelitis Tibiæ with Plugged Cavity in the Tibia of the size of a Hen's Egg accompanying paper on Iodoform Bone-Plugging by Hofrath Prof. von Mosetig Moorhof and Mr. B. Seymour Jones, 152, 153

Three Photoprints and Diagram illustrating use of Hessing's Splint Case Appliance with Steel-bar Traction adjusted to the Left Leg of a Boy with Close Fibrous Ankylosis and Contracture of the Left Knee (case under the care of Mr. T. H. Openshaw), 154, 155

Reproduction of Photograph showing Tumours in Vertebræ and Spontaneous Fracture of Ribs accompanying paper on Myelopathic Albumosuria by C. W. Paget Moffatt, 213

Microphotograph of Plasmodiophora Brassicæ and Plasmodiophora Carcinomatosis, accompanying paper on the Etiology of Carcinoma by Dr. W. F. Robertson and Mr. H. Wade, 216, 217

Diagrams of Operation on the Internus Muscle, showing Divided Extremities in the form of Steps of a Stair and the Extremities united and thereby lengthened for the treatment of Strabismus (Dr. E. Landolt), 254

New Bed and Foot Warmer (Mr. F. Coates), 302

Sterilisable Inhaler for Anæsthetic Mixtures, made for and described by Dr. T. D. Luke, 302

Reproduction of Diagram contained in the Report on Small-pox in Gateshead and Felling, 1903-04, in Relation to Sheriff Hill Hospital, by Dr. G. S. Buchanan, 319

Diagram showing Gastro-jejunostomy and Jejuno-jejunostomy Performed on a Patient suffering from Gastric Ulcer and accompanying a paper on the Septic Origin of Gastric and Duodenal Ulcers by Mr. W. Bruce Clarke, 346

Four Microphotographs of the Thyroid Glands of Fowls and Rats fed on Ordinary Food and also on Raw Meat and Water, accompanying paper on the Rôle of an Excessive Meat Diet in the Induction of gout by Dr. D. Chalmers Watson, 347, 348

Two Illustrations of a Hat-pin 4½ inches long in the Œsophagus producing a False Aneurysm of the Superior Mesenteric Artery, in a case described by Dr. H. D. Rolleston and Dr. T. R. C. Whipham, 356

Diagrams of Lower Lips showing the Mandibular Processes and Recesses in Two Cases of Mandibular Processes associated with Double Hare-lip and Cleft Palate (under the care of Mr. Walter L. Woollcombe), 357, 358

Illustration of a New Apparatus for the Estimation of Urea, described by Dr. William G. Little, 363

Illustration of a case of Urethral Stricture complicated with a Prostatic False Route or Passage, described by Mr. Reginald Harrison, 417

Illustrations of Sections of Seborrhœic Dermatitis Papule and of patch of Psoriasis as seen under the Microscope and showing the Connexion of Seborrhœa, Seborrhœic Dermatitis, and Psoriasis, as demonstrated by Dr. R. W. Brimacombe, 419, 420

Temperature Chart of a case of Endocarditis with Pericarditis following Scarlet Fever and treated by Antistreptococcic Serum, and described by Dr. Alfred R. Spencer, 421

Illustrations of Two Forms of "Turner's Open Thimble": (1) with portion of side cut away; (2) with top and portion of side cut off, 438

Full-length portrait of the late Mr. Luther Holden, F.R.C.S. Eng., 451

Two photomicrographic views of Transverse Sections of the Uvula accompanying description of a Peculiar Form of Chronic Hyperplasia of the Mucous Membranes of the Upper Respiratory Tract by Sir Felix Semon, C.V.O., M.D., 484

Five photoprints of Prostates removed from Octogenarian Patients, accompanying paper on Total Enucleation of the Prostate in Advanced Old Age by Mr. P. J. Freyer, 490, 491, 492

Figures, accompanying paper on Plastic Surgery by Mr. C. R. B. Keetley: (1) Deficiency of Skin over the Left Popliteal Space, 557; (2) Hairy Mole on the Face, 557; (3) Epithelioma of the Jaw, 558; (4, 5, and 6) Amputation of the Leg, 558; (7, 8, and 9) Skin of the Heel Destroyed, 558; (10) a Cicatrix to be removed, 559; (11) a Penis covered with Skin taken from the Scrotum, 559; (12 and 13) Crushed, Torn, and Burnt Fingers, 560; (14, 15, and 16) Cavity left by hollowing out Tuberculous Lower End of a Femur, 560; (17) Cavities in the Tibia, 561; (18) Cavity of the Os Calcis, 561; (19) Forceps arranged round a Free Skin Flap, 562

Four Figures (two full-length Portraits and two Skiagraphs of Legs of a Girl, aged four years, with Severe Curvature in the Tibiæ treated by means of manual osteoclasis by Mr. T. H. Openshaw, 563, 564

Illustration of a Spring Stem Pessary received from Messrs. Maw, Son, and Sons, 578

Illustration of a Portable Lamp on a Tripod Stand for use in Laryngology, described by Dr. Wilfrid Glegg, 578

Two charts, accompanying paper on Industrial Anthrax by Dr. T. M. Legge. Fig. 1, Import of wool, hides and skins, horsehair, and bristles into the United Kingdom in the year 1902, 691. Fig. 2, Monthly return of the total number of animals attacked by anthrax in European Russia, Asiatic Russia, the North Caucasus, and Trans-Caucasus, from January, 1899, to September, 1904, 693

[*List of Illustrations continued on next page.*

LIST OF ILLUSTRATIONS—(*Continued*)

Four illustrations, accompanying Hunterian lecture on the Physiology and Treatment of Surgical Shock and Collapse by Mr J P Lockhart Mummery Fig 1, Chart illustrating a very marked rise in the blood pressure caused by dilatation of the sphincter ani, 700 Fig 2, Chart illustrating a similar result seen during dilatation of the os uteri, 700. Fig. 3, Diagram of blood pressure illustrating Crile's experiment to prove that if shock is produced by exhaustion of the vaso motor centres it should be possible to produce shock by cutting out the action of the vaso motor centres in a healthy animal 701 Fig 4, Diagram of blood pressure showing a similar result obtained when the vaso motor centres are destroyed by pithing an animal, 702 Seven blood pressure charts (Figs 5 to 11), 776–782, five charts (Figs 12 to 16), 847–851

Illustration of Self emptying Spittoon for Railway Carriage Floor, 723

Illustration of a Nasal Inhaler for the Administration of Ether, described by Dr H C Drury and Mr M F Thomson, 724

Illustration of Forceps for Nose and Throat Work and for Opening Peritonsillar Abscess, described by Dr StClair Thomson, 804

Two photoprints of a Soluble Button for Intestinal Anastomosis described by Dr Peter Paterson, 858, 859

Diagram showing Application of Rae's Curvilinear Truss, 867

Illustration of a New Dressing Slab, described by Dr R E Hanson 937

Ph … ture of a Permeated and Distended … companying lecture by Mr W S … of Mammary Carcinoma, 984

Two illustrations of Surface Agar Plates Infected from Active Culture of Staphylococcus Pyogenes Aureus, one of which plates was operated on by "Cyllin Inhalant" and remained quite free of growth (Dr E Klein), 987

Portrait of South African Native with Gunshot Wound of the Nose and Jaw, described by Mr Alexander R Young, 992

Illustration of a Safety Strap for Infants, 1044

Six Micro photographs of the Microscopical Appearance of the Wall of the Gall bladder in Six Cases of Carcinoma and a Semi diagrammatic Representation of the Normal Gall bladder introduced for comparison with the micro photographs, accompanying paper on Gall stones and Cancer by Dr G R Slade, 1060, 1061

Illustration of a Cerebro-spinal Manometer, devised and described by Dr Frank C Eve, 1067

Illustration explaining, especially as regards the Shoulder joint, the Technique of the Conservative Treatment of Tuberculous Arthritis by Professor Dr A Bier, 1092

Three illustrations accompanying account of a case of Excision of the Rectum for Carcinoma Recti by Mr F Wallis, 1119, 1120

Illustration of a cheap Portable Operation Table made by Messrs Arnold and Sons, 1142

Two photo prints (1) General View of Dr O Walther's Sanatorium, Nordrach Colonie, 1165, (2) View of the Speisesaal or Dining hall, 1165, (3) Kiosk at Nordrach containing the only shop, 1233, accompanying account of the Nordrach Colonie Sanatorium by THE LANCET Special Sanitary Commissioner

Two figures showing (1) Rectum and Pelvic Colon with Growth in the Rectum, (2) Rectum pulled through the Anus until the Growth and Healthy Bowel above it were reached, accompanying a case of Abdomino perineal Excision of the Rectum under the care of Mr R W Murray, 1199

Photo print showing façade of the Federal Palace, Berne, where the Committee of the International Association of the Medical Press held its meetings, 1231

Reproduction of drawing after photomicrograph of Red Blood Corpuscles, showing variations in size and shape and diagram of a Viscosity Tube accompanying a case of 'Splenomegalic' or "Myelopathic' Polycythæmia, &c, by Dr. F. Parkes Weber, 1256, 1257

Reproduction of drawing after photomicrograph of "Bacilles Fusiformes et Spirilles" of Vincent's Angina, accompanying paper by Professor H Vincent, 1261

Two diagrams of Pelves, each showing the broad ligament, round ligament sutures and uterus, accompanying paper on the Treatment of Complete Uterine and Vaginal Prolapse by Dr Frederick Holme Wiggin, 1263

Two photo pri … th Spontaneous Amputation des … g 1) Hindu male at … earm, 1331, (Fig 2) … 1331

Illustration accompanying paper by Mr Hubert Higgins entitled "Is Man Poltophagic or Psomophagic" (Fig. 1) Diagram of man's head with a Marey's tambour and lever and a U tube with indiarubber tube and mouthpiece used in experiments to illustrate the functions of the soft palate, 1335, (Fig 2) Apparatus recording the movements of the soft palate consequent on the production of positive and negative pressures, 1336, (Fig 3 Tracings showing positive pressure, negative pressure and alternate positive and negative pressure, (Fig 4) Tracings of poltophagic and psomophagic deglutitions, 1336

Map illustrating the Administrative Stations of the Assistance Publique, Paris, 1353

Photo print of a Uterus in Saggital Section showing Diffuse Adenomyoma, accompanying a Report on 100 Consecutive Abdominal Hysterectomies by Mr J Bland Sutton, 1407

Four figures (Fig 1) Example of "Plimmer's Bodies (Fig 2) Later Stage in Development of "Bodies', (Fig 3) Spermatid of Mouse, (Fig 4) Spermatid of Man, accompanying paper on the Resemblances Existing between the 'Plimmer's Bodies" of Malignant Growths and Certain Normal Constituents of Reproductive Cells of Animals by Prof J B Farmer, Mr J E S Moore, and Mr C E Walker, 1411

Five figures accompanying description of a Regulating Chlorof Inhaler, by Dr A G Levy (Fig 1) Complete Apparatus s from the Front, (Fig 2) Back View, 1413, (Fig 3) Diagram the Apparatus, (Fig 4) Index Hand and Scale, 1414, (Fig Chart showing the Percentages of Vapour in the Chlorof Currents, 1415

Two Photo prints showing Condition of Patient before and after Tr ment in a case of Psoriasis Diffusa under the care of Wheelton Hind, 1420

Illustration of a Portable Electric Lamp for Hospital Use or for Consulting Room designed by Dr J Howard Jones, 1432

Photo print of the "Englefield' Book Support, 1432

Diagrams accompanying P … and their Diagnostic … Action of the intrin … abductor paralysis a … recurrent paralysis, 1482 (Fig Adductor paresis paralysis of the thyro arytenoidei, and parals of the arytenoideus, 1484

Photoprint of legs of patient in a case of widespread ulceration skin and connective tissue, described by Dr W. Bertram Wat 1487

Four figures illustrating the operation of Jejunostomy, with a de tion of a new method by Mr A W Mayo Robson, 1488, 1489

Three charts showing the effects of doses of yeast on the opsonic in and the daily variation in the leucocyte count, accompany paper on the Action of Yeast in Tuberculosis and its Influence the Opsonic Index by Dr W E Huggard and Dr C E Morla 1495

Illustration of an Ice chamber for Freezing Microtomes described Dr N Bishop Harman, 1505

Illustrations accompanying article on Sanitation and the Pana Canal by Mr John G Leigh (Fig 1) General plan of Panama Canal, 1532, (Fig 2) Diagram indicating the origi contour, 1532, (Fig 3) Chart showing absolute influence different factors upon the monthly temperatures on the Isthn of Panama 1598, (Fig 4) Chart showing observed diurnal va tions of temperature, 1599, (Fig 5) Chart of diurnal curve barometric pressure at Alhajuela, 1600

Photoprint of the Otis Electro-cystoscope and diagram of the fi of the Otis Cystoscope and Nitze Cystoscope compared 1570

Two illustrations of an "Elevating Vaginal Director," described by I Arthur J Wallace, 1582

Illustration of a New High Tension Transformer, 1582

Illustration of a Brandy Sterule suggested by Dr Stuart Hallows, 1

Design for rebuilding King's College Hospital, 1668

T … re Frame for Holding Lead foil Shields … ad for the Treatment of Ringworm of … H G Adamson), 1716

Photoprint of a Patient's Hands in a case of Polyarticular "Q Effusion," by Dr T Battersby Jobson, 1717

Chart of Variations in Opsonic Index in a case of Empyema treated Pneumococcus Vaccine (Dr T Glover Lyon), 1718

Illustration of an Emergency Poisoning Case devised by Dr John Wainwright, 1725

Illustration of a Rheostat for Use with the Cytoscope (Dr J Crawf Renton) 1725

ABSTRACT OF

The Oliver-Sharpey Lecture

ON

THE INFLUENCE OF ATMOSPHERIC PRESSURE ON MAN.[1]

Delivered before the Royal College of Physicians of London on April 6th, 1905,

By LEONARD ERSKINE HILL,
M.B. Lond., F.R.S.,
LECTURER ON PHYSIOLOGY AT THE LONDON HOSPITAL MEDICAL SCHOOL.

Mr. President and Gentlemen,—I must first of all acknowledge the honour which the council has done me in inviting me to give this lecture and at the same time express my appreciation of the energy and invention with which Dr. George Oliver has pursued the pathway of research and the valuable stimulus which he has given to future inquirers by founding this lectureship.

My subject naturally divides itself into two parts—the influence of lessened and of increased atmospheric pressure. The one derives its practical importance from mountain sickness and mountain air therapeutics, the other from the sickness of compressed-air workers and the therapeutics of oxygen inhalation. Dr. Theodore Williams as Lumleian lecturer in 1893 set before you the climatic influences of mountain resorts. I shall confine myself to the results of physiological inquiry.

The Effect of Lessening the Atmospheric Pressure; Mountain Sickness.

Analysing the blood gases Bert (1870–80) found the oxygen in the blood was diminished by one-half when the barometric pressure was lowered two-thirds. Several years later Hufner worked out the oxygen dissociation curve of the blood, using purified solutions of hæmoglobin. He concluded that the hæmoglobin remains more than 90 per cent. saturated with oxygen when the barometric pressure is lowered to one-fifth. This dissociation curve of Hufner rendered difficult the acceptance of Bert's explanation of mountain sickness—to wit, oxygen hunger. Hufner himself explained the oxygen hunger by the supposition that a marked difference in oxygen tension between the alveolar air and the blood is required to drive the oxygen through the alveolar wall. Löwy and Zuntz have recently re-investigated the whole matter and have proved that the methods used by Hufner in the preparation of hæmoglobin modify very greatly the oxygen dissociation curve. They found that hæmoglobin solutions hold oxygen much faster than fresh blood and, confirming the results of Bert, have determined that fresh blood shaken with air is only 88 per cent. saturated with oxygen, while the blood in the body exposed to alveolar air (in which the oxygen tension equals 13·5 per cent. of an atmosphere) is only 79 per cent. saturated. Zuntz and Durig have also disproved the above-mentioned supposition of Hufner. Experimenting with frog's lungs they found that a very small difference of oxygen tension (six millimetres) between alveolar air and venous blood is sufficient to maintain diffusion, enough even to satisfy our needs in times of strenuous exertion such as climbing. Mosso and Zuntz and their co-workers have in the last few years carried out a series of exact investigations on themselves while dwelling on the top of Monte Rosa, 4560 metres (nearly 15,000 feet above sea level). They utilised the Regina Margherita hut as a laboratory. In the last expedition of Zuntz and Durig the oxygen tension in Durig's alveolar air fell on the first day as low as 6·3 per cent. of an atmosphere. This makes the oxygen saturation of his blood 65·9 per cent. He suffered from severe migraine and other symptoms of mountain sickness.

It is not so much the quantity as the tension of oxygen in the blood which is of importance under such conditions. This is shown by the fact that an animal whose hæmoglobin has been one-third saturated with CO or from which one-third of the blood has been removed suffers at the same partial pressure of oxygen as a normal animal (Haldane an Lorrain Smith).

Increased pulmonary ventilation is the mechanism by which the alveolar oxygen tension is kept up in high altitudes. The greater the volume of the tidal air the more does the composition of the alveolar air approximate to that of the external air. A deep breather can thus attain to far higher altitudes than a superficial breather (Löwy). Shallow breathing animals such as rabbits die if kept for more than three days at 350 mm. Hg. (6000 metres altitude) and their organs show marked signs of fatty degeneration (Lewinstein, Schrötter). The mountain climber needs a powerful heart rapidly to circulate blood through his lungs and requires to be a deep breather, otherwise he suffers from oxygen hunger. Hence the varying altitudes at which different men are affected. Climbing enormously increases the oxygen use. Resting in Berlin Zuntz used 232 cubic centimetres oxygen per minute; while climbing a glacier on Monte Rosa he used 1329 cubic centimetres. His pulmonary ventilation increased from 4·755 litres per minute resting at Berlin to 7·613 litres resting on Monte Rosa, and to 46·74 litres while climbing the glacier. Hence the aggravation of mountain sickness by exertion.

Training makes an enormous difference. The heart and respiratory mechanism become adjusted to the enormous demands made upon them. The surplus body weight is reduced and the load to be lifted thus lightened. New movement complexes are established and carried out with the maximum of economy. A trained athlete can turn 30 per cent. of his total energy into external work, an untrained man only 10 or 15 per cent. The untrained man becomes over-heated. Owing to the diathermancy of the upper regions of the air due to its freedom from dust and vapour the radiant heat of the sun is very great. This and the muscular work of climbing together may raise the body temperature of the town dweller to 103° F. (Pembrey, Arkle)—a temperature which by itself will lead to breathlessness. It is well known to climbers that windless sun-heated valleys and gullies produce more sickness than exposed ridges. Conway recommends climbing by night or cloudy days. On the other hand, an Alpine soldier of splendid physique and trained to mountaineering carried 40 kilogrammes up the glacier of the Gnifetti peak with a rise of temperature not greater than a few points of a degree (Mosso). Manca, after 70 days' training with dumb-bells, found he could do five times the work he could do on the first day. The CO_2 output produced by climbing Berne cathedral was increased fourfold at first and only threefold after training (Kronecker). A debauch makes a great difference in the capacity of a man to climb or endure high altitudes. A soldier who could lift 5 kilogramme dumb-bells 104 times on Monte Rosa, after a drinking bout could only lift them 67 times and his pulse accelerated much more than when in good condition.

The observations of Zuntz and his co-workers show that the respiratory metabolism is increased from 15 to 30 per cent. in town dwellers while dwelling on the top of Monte Rosa. This increase is not due to cold, insolation, or light of the snowfields, for it persisted while the members of the expedition rested within the warm Alpine hut. Not only the resting metabolism but that during muscular exertion is increased. The metabolism in walking on the level snow-covered ground was contrasted with walking under similar conditions in Vienna.

The increased metabolism did not come on until the second day after reaching the Monte Rosa hut. This delay explains why a similar increase has not been observed in pneumatic chamber experiments (Löwy) or balloon expeditions (Zuntz and Schrötter). Part of this increased metabolism may be attributed to the increased respiratory work and the greater rapidity of the circulation. Part is probably due to nervous exaltation produced by the strange surroundings and bracing air. The high electrical potential of the air on mountain peaks has been considered as a possible cause but without the production of definite evidence. Alpine soldiers showed no increased CO_2 output on Monte Rosa (Mosso).

By lower oxygen tension than 6 to 7 per cent. of an atmosphere the metabolism becomes deranged as evidenced by rise of respiratory quotient, appearance of lactic and oxalic acids in the urine (Terray), increased nitrogen output (Fraenkel and Geppert), and fatty degeneration of organs. Death quickly occurs when the oxygen tension falls to 3 to 4 per cent. of an atmosphere. Diminution of the barometric pressure has no mechanical effect on the circulation (Fraenkel and Geppert). The pulse is always accelerated in high altitudes and irregular rhythm of respiration or Cheyne Stokes respiration often occurs on resting or sleeping. The latter is probably due to the diminished alveolar tension of CO_2, which is the prime regulator of the rhythm of respiration (Haldane). Pembrey has found that Cheyne Stokes respiration can be abolished by increasing the percentage of CO_2 in the respired air. The blood counts are increased by short exposures to low barometric pressures owing to congestion of the blood in the peripheral parts and increased concentration produced by transudation of plasma. The increase is not found in blood taken from the arteries. Exposure for many days causes increased formation of hæmoglobin; the percentage of iron in the liver diminishes and that in the blood rises. The inhabitants of the lofty Peruvian plateaux are stated to have a million or two more corpuscles per cubic millimetre than dwellers on the plains (Viault). The therapeutic effect of mountain climate depends on the purity of the air, its freedom from dust and bacteria; on the bracing cold and intense insolation, on the strengthening of the heart and respiratory mechanism; on the increased formation of hæmoglobin; and on increased respiratory metabolism.

---

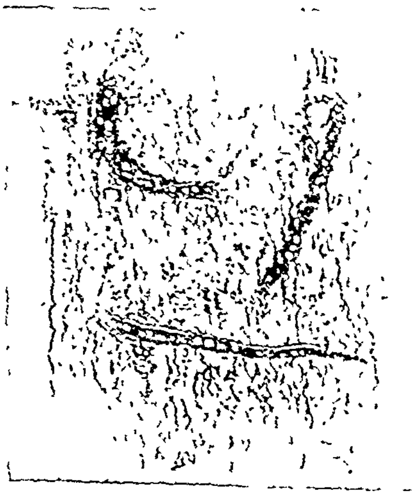
The Effect of Compressed Air. Caisson Sickness and Divers' Palsy

The rate of metabolism of an animal cannot, like a fire, accelerated by increasing the supply of oxygen (Pflüger). The researches of Regnault, Hermann and Lehmann, Terray, and Löwy have recently been confirmed by Durig who has used the most exact methods of experiment. He finds that oxygen tensions varying between 11 per cent. and 94 per cent. of an atmosphere have not the slightest effect on the respiratory exchange of man. The inhalation of oxygen or exposure to compressed air cannot, therefore, be used as a *therapeutic agent to increase the normal rate of metabolism.* Cases of dyspnœa where the oxygen in the blood is deficient and the tissues are suffering from oxygen hunger may, of course, be benefited.

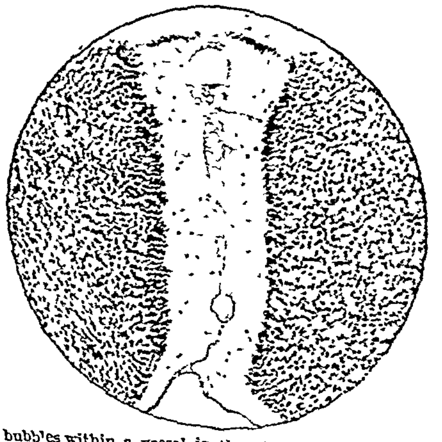
FIG. 6.



Gas bubbles in the capillaries of the spinal cord (Schrötter).

The continued action of oxygen above 100 per cent. of an atmosphere acts as a protoplasmic poison. It produces *inflammation* of the lungs (Lorrain Smith, Hill, and Macleod), depresses the CO_2 output, and lowers the body temperature. Haldane and Lorrain Smith, from experiments on the comparative absorption of O_2 and CO (mixed in known proportions) by shed blood and blood in the living animal have concluded that the lung has the power of actively absorbing oxygen and of forcing it into the blood at a tension higher than that in the alveolar air. This power Lorrain Smith finds is abrogated by exposure to oxygen tensions of 170 to 180 per cent. of an atmosphere.

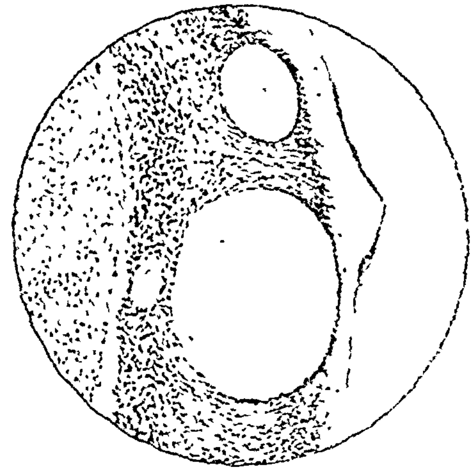
FIG. 7.



Gas bubbles within a vessel in the pia mater of the brain. The corpuscles are driven within the middle part of this vessel and a bubble appears at either end.

The lungs after exposure to high pressure oxygen show congestion of the alveolar capillaries, hæmorrhagic exudation, and consolidation. The pneumonia is patchy if quickly and universal if slowly developed. It requires about 24 hours at eight atmospheres of air (= oxygen 168 per cent. of an atmosphere) to produce marked pulmonary congestion. In animals that survived three days the alveoli and bronchioles showed an exudation containing numberless polymorphonuclear leucocytes, cocci in abundance, and shed alveolar cells (Bulloch and Hill). The use of oxygen inhalations in pneumonia thus finds little scientific evidence in its favour. The epithelium of the swim-bladder of deep sea fish is immune to high pressures of oxygen. The "red body" of the bladder secretes oxygen and in a fish caught at 4500 feet depth the tension of oxygen must have equalled 127 atmospheres. This shows that protoplasm can adapt itself to withstand an enormously high pressure of oxygen, just as it can be evolved to withstand a temperature of 70° C. or the high percentage of salts in the Dead Sea.

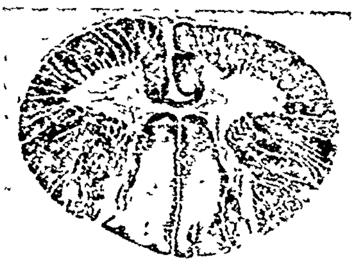
FIG. 8.



Gas bubbles within the cortex of the cerebrum compressing and flattening the surrounding nerve cells.

The muscle and heart and nerves of the frog survive exposure to from 50 to 60 atmospheres O_2 for an hour or even longer. The heart beats become gradually weaker and the muscle curve resembles that of fatigue. All terrestrial animals are instantly thrown into convulsions resembling those of acute asphyxia by exposure to from 50 to 60 atmospheres O_2. Exposure of mammals to from three to five atmospheres O_2 produces in from 10 to 20 minutes tetanic convulsions of great severity and, finally, a dyspnœic type of respiration, coma, and death (Bert, L. Smith, Hill and Macleod).

FIG. 9.

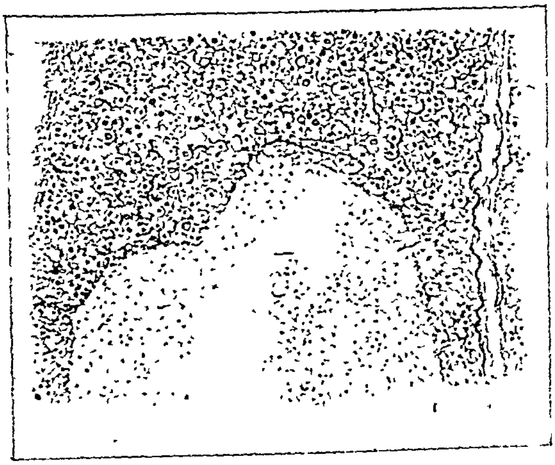


Lesion produced by gas bubbles in the spinal cord of a diver who was stricken with paraplegia after ascending from a depth of 40 metres (130 feet; five atmospheres) (Schrötter).

Analyses of the blood gases show that nitrogen is absorbed by the blood of an animal exposed to compressed air according to the law of partial pressures (Bert, Schrötter, Hill and Macleod). Under one atmosphere 100 cubic centimetres of blood dissolve 1·23 cubic centimetres of N_2; under four atmospheres 4·92 cubic centimetres of N_2. The same blood gives up 3·69 cubic centimetres of N_2 when decompressed from four atmospheres to one atmosphere. The whole blood in the body of a man weighing 70 kilogrammes would give up about 130 cubic centimetres of N_2. His tissue fluids would yield ten times as much.

The study of the circulation has been carried out by recording manometers placed within the pressure chamber or by microscopical examination of the web of the frog's foot stretched over the window of the chamber. The observations so made show that the compressed air has no mechanical effect on the circulation. The pressure is instantly and equally transmitted to all parts of the body by the fluids of the body. All mechanical congestion theories of the cause of caisson sickness are therefore erroneous (Hill and Macleod). In the case of divers and caisson workers every ten metres of water depth equal one atmosphere. A man working at a depth of 100 feet is exposed to about four atmospheres of air pressure. The study of the effects of rapid decompression shows that the cause of caisson sickness and divers' palsy is the setting free of the air which has dissolved in the blood and tissue fluids under the influence of the pressure. This forms bubbles and produces air embolism. The symptoms only occur after the men have returned to the surface. The gas so set free is chiefly nitrogen, for the oxygen is quickly absorbed by the blood and tissues. Analysis of the gas obtained from the right heart of a dog yielded 15·2 per cent. CO_2, 82·8 per cent. N_2, and 2·0 per cent. O_2. This animal was instantaneously decompressed by the bursting of the chamber. Enormous subcutaneous emphysema was found with gas in the stomach, omentum, anterior chamber of eye, spinal cord, cerebrospinal fluid, &c. (Bert, Schrötter, Hill and Macleod). The formation of the air bubbles can be observed in the capillary circulation of the web of the frog's feet. To watch the bubbles of air scurrying through the capillaries first one or two and then many until the vessel is filled with air is one of the most interesting sights I have ever witnessed.

FIG. 10.



The lesion seen under a high power showing the necrosis of the nervous tissue (Schrotter).

Recompression drives the gas bubbles again into solution and allows the circulation to recommence. Similarly recompression can be applied in cases of caisson sickness and divers' palsy but it must obviously be applied very rapidly or the effects of the ischæmia will persist. Post-mortem examination of the spinal cord in cases of divers' palsy shows the existence of necrotic patches surrounding the spaces in which air-bubbles collected after decompression (Catsaras, Schrötter). Recompression chambers have been used with advantage in some caisson works (Moir, Schrötter). Gradual decompression allows the dissolved gas to escape from the lungs and prevents the formation of bubbles in the blood. By making, therefore, the period of decompression last one hour, or for very deep work two hours, all caisson workers and divers can be entirely relieved from the risks of paralysis or death.

I have, with Messrs. Siebe and Gorman's coöperation, designed a diving-bell into which divers can enter and inclose themselves after completion of their work. Hoisted on to deck in this bell they can be slowly decompressed. The use of this bell will allow divers safely to reach greater depths than at present. Caisson works must necessarily possess an air-lock in which the men are compressed or decompressed on entering or leaving the works. The times of decompression used by engineers are at present far too short. Five, or at most ten minutes, is the period commonly used. Knowing as we now do the cause of caisson sickness the responsibility of preventing such sickness should be thrown upon the contractors of caisson works.

Oxygen gas might be used to replace the air in the airlock so as to wash the nitrogen out of the tissue fluids and blood. This would allow the period of decompression to be greatly accelerated, for owing to the oxygen-carrying power of the blood there is little danger of oxygen bubbles producing embolism (Schrötter, Hill and Ham). Against this practice, however, is to be put the toxic action of high pressure oxygen on the lungs and central nervous system. It would not be safe to expose a man to three atmospheres of oxygen for more than a few minutes.

Stress has been laid by Snell on the importance of the CO_2 tension in the air breathed by caisson workers. He says that in the caissons of the Blackwall Tunnel an increase of CO_2 tension of 0·1 per cent. of an atmosphere produced caisson sickness and that thorough ventilation proved effectual as a preventive means. C. Ham and I have recently investigated this matter. A tension of CO_2 of 4 per cent. of an atmosphere, as is well known, produces marked dyspnœa. This, we find, is so whether an animal be exposed to one or to several atmospheres of air. We enclosed a cat in the chamber without supplying any ventilation and allowed the percentage of CO_2 to reach 4 per cent. We then raised the air pressure in the chamber to four atmospheres; the CO_2 percentage (obtained by analysis of the air drawn from the chamber) fell to 1 but the tension (1×4) remained the same and so did the signs of dyspnœa. We then allowed three atmospheres of air to escape; three-quarters of the CO_2 thus escaped, the tension of CO_2 fell to 1, and the dyspnœa ceased. Such high tensions of CO_2 as from 1 to 4 per cent. seemed to have no influence on the danger of decompression. The effect of bad ventilation in caissons may possibly be due to CO arising from flare lights or to H_2S arising from the soil. Any factor which leads to exhaustion of the worker, such as overheated air saturated with moisture, must increase the danger of rapid decompression by lowering the efficiency of the pulmonary ventilation.

In carrying out our researches Professor Macleod and myself have been greatly indebted to Messrs. Siebe and Gorman, who have given us the use of air pumps and chambers and the benefit of their unequalled experience as submarine engineers.

Lectures
ON
CARBOHYDRATE METABOLISM.

A Course of Advanced Lectures in Physiology, delivered at the University of London,

BY F. W. PAVY, M.D. LOND., LL.D. GLASG., F.R.S.,

HONORARY PHYSICIAN TO KING EDWARD VII. HOSPITAL; CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

LECTURE II.[1]

GENTLEMEN,—The deduction to be drawn from what has preceded is that saccharose, lactose, and maltose, reaching the circulatory system as such, remain untouched and simply filter off with the urine. Their molecules, it may be considered, are not of a nature to possess attraction for, and to be taken on by, the bioplastic molecules with which in the circumstances they are brought into contact. Galactose, lævulose, and dextrose, on the other hand, must be regarded as possessing an affinity for bioplasm which renders them susceptible when similarly placed of being to a greater or less extent assimilated or taken on by it instead of being wholly rejected. Although thus much is permitted to be said, yet the experimental evidence which has been adduced shows that the conditions existing only lead to a more or less tardy and incomplete assimilation, whence it arises that even in the case of dextrose, the most assimilable of the three sugars, a certain amount of escape occurs with the urine.

---

[1] Lecture I. was published in THE LANCET of June 24th, 1905, p. 1704.

The experiments with the injection of a quarter of a gramme of dextrose per kilogramme are instructive upon this point. The blood from the instantly killed animal gave the figures 2·400 per 1000 before and 2·660 per 1000 after hydrolysis; that from the animal killed five minutes after, 2·333 and 2·910 per 1000; and from the animal killed at the end of 15 minutes, 1·430 and 2·040 per 1000. With the introduction of even so small an amount as $\frac{1}{4000}$th of the body weight, after the lapse of a quarter of an hour the blood had not returned to its normal condition but the sugar present in it had a lower cupric oxide reducing power than it had at first. In the case of the animals that were allowed to live for 60 minutes after the injection the blood also showed in an unmistakeable manner the existence of a larger amount of sugar than is normally present. From this it follows that when sugar reaches the circulation instead of being at once appropriated it only makes a tardy disappearance and during this time its presence is being revealed by the state of the urine. Looking at the table showing the condition of the urine secreted during the 60 minutes the amount of sugar is seen to stand definitely higher than in normal circumstances. In one instance the figures stood at 12·56 per 1000 before and 18·20 per 1000 after hydrolysis. There was an instance in which the figures stood at 2·28 and 5·67 per 1000, which is in conformity with the normal, but here there was quite an exceptional flow of urine, and reckoning for outflow and proportionate amount present the quantity of sugar found constituted 11·3 per cent. of that injected. Some of this would be naturally due to normal sugar elimination.

Instructive results were likewise given by the one gramme per kilogramme subcutaneous injections. Here the dextrose would only be gradually absorbed and even at the end of two hours, when the animals were killed, examination of the subcutaneous tissue at the seat of injection showed that marked sugar impregnation still existed. The blood at the time named gave a distinctly higher indication of sugar than is normally found. The urine varied considerably, which is not surprising, as there are many factors that influence the secreting activity of the kidney. Where large quantities of sugar are eliminated the diuresis evoked forces elimination, but in contrary circumstances through inactivity of the kidney only a restricted outflow may occur. To quote the highest sets of figures obtained before and after hydrolysis they ran as follows: 11·20 and 22·40 per 1000, 16·30 and 22·80, 13·60 and 24·00, and 12·38 and 25·60.

I consider that the evidence supplied by the line of research to which I have just been referring unequivocally shows that sugar reaching the circulation cannot escape filtering off with the urine on passing through the kidney, and yet it is contended that the carbohydrate of our food finds its way through the circulatory system in the form of sugar to the tissues for consumption. If this really occurred it could not fail to be attended with glycosuria. Undoubtedly the carbohydrate must in some way or other reach the tissues for it is here where utilisation of it occurs. The information supplied by the respiratory quotient affords evidence of the carbohydrate of the food actually reaching the seat of utilisation in the tissues. With carbohydrate matter consisting of carbon and of hydrogen and oxygen in the proportion to form water there is only the carbon free for oxidation and the oxygen utilised gives rise to an equal volume of carbon dioxide. Thus, if carbohydrate were the only material oxidised the intake of oxygen and the output of carbon dioxide would stand equivalent. In the case of fat and proteid there are other elements to undergo oxidation and thus a portion of the intake of oxygen will be applied to this purpose and render the output of carbon dioxide proportionately less. Now, observation shows that the larger the amount of carbohydrate entering into the constitution of the food the nearer, in accordance with the principle expounded, does the respiratory quotient approximate to the unity point.

From these considerations the difficulty has to be faced that the carbohydrate of the food has to reach the tissues and that if it passed, as has hitherto been taught, through the circulatory system in the form of sugar it would flow off with the urine as it does in diabetes. Let us suppose for a moment that the food carbohydrate really took the course that has been mentioned. Could this possibly occur without any indication of it being afforded by the state of the blood and the urine? We have seen that no definite relationship is to be traced in the healthy animal between the food and the state of the blood and urine. It is true that the amount of blood sugar came out rather higher for the rabbit than for the cat, the mean of the observations recorded being 1·089 per 1000 before hydrolysis and 1·495 per 1000 after for the one against 0·880 and 1·140 per 1000 for the other; but in the case of both animals the figures stood decidedly higher for the thoroughly fasting than for the fed state, being 1·21 per 1000 before hydrolysis and 1·64 per 1000 after for the rabbit and 1·10 and 1·15 per 1000 for the cat. As regards the urine the same order occurred in the fed state as was noticeable for the blood, the figures being 3·69 per 1000 before and 7·03 per 1000 after hydrolysis for the rabbit and 2·75 and 5·67 per 1000 for the cat. In the fasting state the urinary figures were 2·23 per 1000 before and 4·80 per 1000 after hydrolysis for the rabbit and 4·19 and 8·65 per 1000 for the cat.

Without any food, then, to supply sugar for transit through the circulation the amount of sugar in the blood is seen to be higher than when food was being taken. There is much variation in our own food at different times, but the urine reveals nothing to show it. Voit gives as a normal daily diet for man 118 grammes of proteid, 56 grammes of fat, and 500 grammes of carbohydrate. The urine with this diet gives no further evidence of the presence of sugar than after animal food or no food at all. Can the 500 grammes of carbohydrate pass through the circulatory system to the tissues in the form of free sugar without affording evidence of its doing so through the medium of the urine? We have seen from the experiments with the intravenous injection of a quarter of a gramme of dextrose per kilogramme how sensitive the urine is to the presence of sugar in the blood, and surely the transit of 500 grammes per diem in the human subject from the food ought not to leave the urine in the same state as when there is no food carbohydrate passing, as would happen in a day of fasting. I am not oblivious of the alleged glycogenic function of the liver, but if the liver detained the carbohydrate and subsequently gave it out as sugar this would not prevent the system from being, at some time or other, traversed by the sugar, with the result of a proportionate appearance of sugar in the urine.

It is necessary for service in the economy that the food carbohydrate should reach the tissues, but the transport must be in some other way than as free sugar in the blood, seeing that sugar passing to the tissues would at the same time pass to the kidney and filter off with the urine as it does in diabetes. If sugar entered the blood nothing short of immediate assimilation by it would suffice to prevent the kidney being reached, but assimilation is looked upon as taking place in the tissues and this involves passage of sugar through the circulation.

I do not think the distinction between assimilation and utilisation is kept as clear as it should be. Often it seems as if from the manner in which the word assimilation is used that it implied utilisation. In reality it only implies a taking into, and incorporation with, the material that performs the assimilative duty. Utilisation is a subsequent process and it need not necessarily take place immediately. The one is a process of synthesis which has come to be regarded as dominated by enzyme action, for to enzyme action is now assigned the office of governing factor of building up as well as of breaking down; the other is a process of breaking down with which oxidation is associated. Both the material to be oxidised and the oxidising agent enter the molecular complex within which the oxidation occurs, not presumably in a direct manner by one step but by successive steps of degradation with the formation of various intermediate products before carbon dioxide, water, and ammonia are reached.

It may be said, therefore, that both oxygen and the material to be oxidised are assimilated by the bioplastic molecule within which they constitute the basis for metabolic action. Evidence is afforded of oxygen being taken and stored up by the molecule, in a form to be ready for use when required, by the increase of weight that has been observed to occur in a marmot during profound hibernation and by the discharge of carbon dioxide that has been noticed to persist for some time from a frog placed in an atmosphere of nitrogen and therefore cut off from obtaining an intake of oxygen. Without the storage to some extent of both foodstuff and oxygen by assimilation or incorporation into the molecule there would be no provision for stability of molecular action.

Seeing that the requirement exists for the carbohydrate of the food to reach the tissues where utilisation occurs and that it is incompatible with the circumstances that present themselves for it to pass through the circulatory system as free sugar we are faced with the problem of how the transport is in reality made. This is the matter to which I will now proceed to direct attention and I think it will be found that an explanation can be given which satisfactorily meets all the circumstances.

It has long been known in connexion with the vegetable kingdom that a class of bodies exists into which carbohydrate enters as a component part. The bodies are called glucosides and with the advance of chemical knowledge they have been found to constitute a very numerous and widely distributed group. By chemical means the carbohydrate can be recovered from them, but in the characters they possess there is nothing for a moment suggestive of its presence, so completely does the carbohydrate lose its identity. Until recently it has not been surmised that a similar state of things holds good in connexion with products from the animal kingdom. Landwehr at the commencement of the 1880-90 decade obtained a carbohydrate from mucin which he styled "animal gum." He invested the product with a variety of visionary attributes but did not concern himself about it as a constituent of the parent substance. In the early part of the following decade, whilst engaged in the pursuit of my investigations upon the relations of sugar in the animal system, I came across evidence pointing to proteid matter in connexion both with the animal and vegetable kingdoms being of a glucoside nature. The matter was dealt with in my "Physiology of the Carbohydrates," published in 1894, having previously formed the subject of a communication entitled, "On the Glucoside Constitution of Proteid Matter,' presented to the Royal Society in the preceding year.

By the research conducted it was shown that carbohydrate was susceptible of being obtained from proteid by the breaking-down action of both potash and sulphuric acid, the product in the former case presenting itself in the amylose form and in the latter as sugar. A demonstration was afforded through the medium of the several distinguishing properties observed that the product obtained was in reality of a carbohydrate nature. The albumin and vitellin of the egg, the proteids of the blood serum, and fibrin from the animal kingdom; and from the vegetable kingdom, gluten from wheat flour, and the proteid of the haricot bean were found to yield cleavage carbohydrate. None was obtainable from gelatin and only an insignificant amount from casein. To begin with, as is not unusual in like circumstances, dissent was raised to the proposition I had put forward but I think it may be taken to be now generally accepted. Indeed, gluco-proteid is a term that is found to have fallen into general use.

It was not the mere chemical fact of carbohydrate being a component of proteid that constituted the point of interest to me. I saw in it a bearing of deep physiological importance in connexion with the application of carbohydrate within the animal economy and it was this that riveted my attention to the matter. I knew that carbohydrate underwent utilisation in the tissues and that a means of transport for it from the alimentary canal must exist that would not permit of its filtering off with the urine. The entry of carbohydrate into the construction of the proteid molecule I could see provided what was wanted and gave the clue to the solution of the difficult problem that had hitherto faced us. Locked up in proteid, carbohydrate is in a safe position for escape from being discharged with the urine, on account of the proteid molecule being too large to pass off by filtration.

The importance of the subject has prompted me to return to it and to conduct further work in connexion with it. This I have been lately carrying out in the physiological laboratory of the University of London, where I have found every facility provided to aid its prosecution. The work has branched out into collateral channels and has called for a considerable amount of steady labour in which I have received the able and zealous help of my assistant, Mr. H. W. Bywaters. The first point to be dealt with is the presence of carbohydrate as a component part of different animal proteids. I will afterwards give attention to the physiological bearings belonging to the information that has been experimentally obtained. It will be understood that we shall be now looking at carbohydrate matter from an opposite point of view to that from which it has hitherto been commonly regarded—namely, as proceeding in the building up or anabolic instead of the breaking down or katabolic direction.

It is the locked-up carbohydrate that has to be searched for and the combination has to be broken down before any information can be obtained. After the carbohydrate has been set free the next step is to place it in a position to be susceptible not merely of recognition but of quantitative determination. It is brought to the state of sugar for the attainment of the object in view and in order that the sugar may be satisfactorily estimated there must be nothing finally present to interfere with the application of the ammoniated cupric test. I have now had much experience in connexion with this matter and consider that with careful manipulation trustworthy results are obtainable. For years past I have been in the habit in blood examinations of estimating the amylose (proteid) carbohydrate as well as the sugar, and in my "Physiology of the Carbohydrates" I made special allusion to the fact of an increase being observable as an accompaniment of the presence of an excess of sugar, looking as though a portion of the sugar had passed into an assimilated state whilst in the blood.

The proteid carbohydrate may be separated by the breaking-down agency of potash and by that of hydrochloric acid. With the ordinary proteids the results given by the two processes on subsequent estimation fairly agree. In the case of the mucoids, however, there is great disparity and the information supplied points suggestively to the existence of a certain constitution of the molecule. Something requires to be said regarding the method of procedure for estimating the amount of proteid carbohydrate present in different circumstances, as the matter is related to a line of investigation which seems to me to have a promising character and which as yet has not been touched by others and is therefore not to be found referred to in books.

Estimation of Proteid Carbohydrate by the Potash Process.

When liquid blood is the material to be analysed about 30 grammes is a convenient quantity to employ. After being weighed out into a 400-cubic centimetre flask, it is treated with a potash solution so as to give to the mixture a 10 per cent. strength. In the case of the solid proteids from one and a half to two grammes and of dried blood three grammes may be taken. After thorough drying the material requires to be brought to a minutely divided state in order to secure full action of the chemical agent, which is an essential point. The reduction is effected by rubbing down in a mortar and passing through a fine metallic gauze sieve (90 to the linear inch). The weighed product is next treated with about 35 cubic centimetres of a 10 per cent. potash solution and subjected to boiling for half an hour under a reflux condenser in a flask of about 400 cubic centimetres capacity which provides against the inconvenience arising from the foaming that occurs. The contents of the flask are now poured into ten volumes of methylated spirit (95 per cent.) contained in a tall beaker and the flask is rinsed out with more spirit. The beaker is allowed to stand till the following day for the precipitate to settle. Filtration is next performed through asbestos arranged in a Gooch's perforated porcelain crucible adapted to an exhausting filter pump. Much time is saved by decanting the clear liquid and filtering this first, as the precipitate, on being poured on to the filter, clogs it and impedes filtration. After washing with spirit the next step is to subject the precipitate, which contains the proteid carbohydrate in the amylose form, to the hydrolysing influence of a boiling mineral acid. Hydrochloric acid of 5 per cent. strength is used for this purpose. The precipitate is washed with the hot acid, which dissolves it, from the asbestos plug in the crucible into the beaker originally used for precipitation, the last traces being removed by repeatedly pressing out the liquid from the asbestos by squeezing it with a glass rod against the side of the crucible. After heating the acid solution in the beaker to the boiling point to get rid of the adhering traces of spirit the liquid is transferred to a small flask (about 150 cubic centimetres) into which the washings of the beaker are also poured. The contents of the flask, measuring about 50 cubic centimetres, are next boiled for one and a half hours under a reflux condenser. When cold the liquid is nearly neutralised with potash, clarified by boiling with hydrated alumina[2] made to 75 cubic centimetres and thrown on to a dry filter. The filtrate is rendered faintly alkaline by the addition of a drop or two of strong alkali, filtered from any slight precipitate, and titrated with the ammoniated cupric test. The liquid for titration should be of a pale sherry colour and should give no biuret reaction on being titrated. Summarily stated the process consists of breaking down the proteid with potash, precipitating the liberated amylose carbohydrate by means of spirit, converting into sugar, and estimating this in the usual way.

---

[2] Vide Pavy: The Quantitative Estimation of Sugar in Blood,' Journal of Physiology, vol. xx., 1896.

Estimation of Proteid Carbohydrate by the Hydrochloric Acid Process.

In the potash process when blood is taken it is not essential that it should be first of all treated with spirit to remove the sugar as the potash exerts a destructive action upon it and in this way gets rid of it. Such is not the case with the acid process and before treatment with the acid the removal of the sugar present must be effected. The blood (say 30 grammes) should be extracted and washed with methylated spirit with the use of a press as in the process adopted for the quantitative determination of sugar in blood. The coagulated mass obtained is treated with strong hydrochloric acid and allowed to stand overnight to become thoroughly liquefied, then diluted down to a 10 per cent. strength, having reckoned for 100 cubic centimetres volume as the quantity to work with, and afterwards boiled under a reflux condenser for one and a half hours. A dark-coloured liquid is obtained containing the nitrogenous products of disintegration as well as the sugar. The point now to be attained is to remove the nitrogenous products and to leave the sugar. Here a certain amount of difficulty is encountered on account of the soluble nature of the principles to be dealt with. Phosphotungstic acid is the best precipitant. A 20 per cent. solution is added till it no longer gives a precipitate. The resulting admixture is heated to boiling for the purpose of facilitating subsequent filtration by causing the precipitate to assume a more granular form. What is next wanted is to remove the phosphotungstate compound but as this is not completely insoluble, and particularly when hot, the process is more lengthy than it would otherwise be and at the same time steps must be taken to provide as far as possible against loss of sugar by its remaining attached to the precipitate. Hence filtrations (best on what is known as a glass filter plate), rubbing down in a mortar, and adequate washing are required to be performed. Subsequently the liquid obtained after being nearly neutralised with sodium hydrate is evaporated down over a water bath to a small bulk and allowed to stand overnight for settlement out to occur. Filtration is now conducted with asbestos, a Gooch crucible, and an exhausting pump, the washing being effected with a saturated solution of sodium chloride to prevent any phosphotungstate precipitate being taken up. The filtrate has now to be made slightly alkaline with sodium hydrate and as this is done a deep blue colour is developed. The colour that is developed might perhaps, without the employment of litmus or other such-like agent, suffice to indicate that alkalinity has been reached but in my own work it has not been relied upon for this purpose. On exposure to air the colour disappears and the disappearance is accelerated by passing air through the liquid. All that remains to be effected now is to bring to a known volume, as, for instance, 75 cubic centimetres, throw on to a dry filter, and titrate. When properly prepared the liquid is colourless and gives no biuret reaction on titration.

Having described the processes for quantitatively determining the proteid carbohydrate obtainable by the breaking-down action of potash and hydrochloric acid I will now proceed to deal with various products and to show how they stand under subjection to the treatment in question:—

Proteid Carbohydrate obtained by Cleavage with Potash and Hydrochloric Acid. (The figures in each case represent parts per 1000 with the carbohydrate expressed as glucose.)

Dried defibrinated blood (serum and corpuscles) from the horse.—The blood was defibrinated, poured into methylated spirit, the coagulum collected, pressed, washed with boiling spirit, dried, and powdered.

Cleavage by potash.		Cleavage by hydrochloric acid.
21·9	... ...	19·7
20·4	... ...	20·6
21·2	... ...	20·7

Dried plasma of horse's blood.—The blood on collection was treated with 1 per cent. strength of citrate of potash to prevent coagulation and centrifugalised. The plasma was afterwards dealt with in the manner described for the defibrinated blood.

Cleavage by potash.		Cleavage by hydrochloric acid.
25·8	... ...	25·6

Dried blood corpuscles.—The corpuscles were obtained by centrifugalising the citrated blood and washing with normal saline solution. They were then treated with spirit and subsequently prepared in the usual way. The first two sets of figures refer to horse's blood and the last two to cat's blood.

Cleavage by potash.		Cleavage by hydrochloric acid.
4·5	... ...	3·2
3·3	... ...	2·9
4·5	... ...	1·9
5·2	... ...	2·5

It is noticeable that the yield of proteid carbohydrate by the corpuscles is in striking contrast with that yielded by the other portions of the blood, the amount being quite of an insignificant character. It may be remarked with regard to the lower figures obtained after cleavage by hydrochloric acid in comparison with those after cleavage by potash that the bulky phosphotungstate precipitate, from the difficulty offered in thoroughly washing out the sugar, may have had something to answer for in connexion with the result. Looking at the relative yield from the defibrinated blood and plasma it is in accordance with what might be looked for in view of the presence of the corpuscles in the former and not in the latter case.

Serum globulin.—The colourless serum from horse's blood was treated with an equal volume of saturated ammonium sulphate solution. The precipitate was collected, treated with water to dissolve, and the globulin reprecipitated with ammonium sulphate. Water was again added to dissolve, and the globulin was now precipitated from the liquid by boiling. The coagulated globulin was afterwards washed with boiling water to remove the saline matter and then treated with boiling spirit. It was finally dried and powdered.

Cleavage by potash.		Cleavage by hydrochloric acid.
25·1	... ...	25·1
30·5	... ...	30·2

Serum albumin.—The filtrate from the serum globulin just dealt with was diluted with water and, after acidifying with acetic acid, heated to boiling. The coagulated albumin was collected, pressed, and adherent ammonium sulphate washed out with boiling water. After treatment with boiling spirit it was dried and powdered.

Cleavage by potash.		Cleavage by hydrochloric acid.
18·4	... ...	17·7
20·8	... ...	19·3

Globulin, it is thus seen, gives a higher yield of proteid carbohydrate than albumin, but this is all that can be said. Contrary therefore to a statement opposed to my original results, which I find is obtaining currency in print, albumin gives a notable yield.

Blood fibrin.—The clot from horse's blood was washed with water till practically colourless. It was then dehydrated with boiling spirit and afterwards dried and powdered:—

Cleavage by potash.		Cleavage by hydrochloric acid.
25·8	... ...	23·1

Egg Proteids.

The egg proteids, alike from the yelk and the white, do not materially differ as regards their yield of carbohydrate except in one instance—viz., ovomucoid, in which a very different state of things exists from that met with ordinarily. Not only in this instance is the yield of carbohydrate signally large but apparently it is derived from a double source—viz., from carbohydrate in the form of sugar as well as from carbohydrate in the amylose form. The matter will be subsequently discussed under the head of ovomucoid but I refer to it now as it probably affords the explanation of the difference in the results obtained from the crude material of the egg and the isolated proteid principles.

Crude egg yelk.—The egg yelk was treated with methylated spirit and the precipitate repeatedly boiled with fresh quantities of spirit with the view of getting rid of the major portion of the fat. The yelks were not completely freed from adhering white which may possibly account for the higher figures after the acid cleavage.

Cleavage by potash.	Cleavage by hydrochloric acid.
27·0	32·7
25·3	29·9
26·7	31·9
27·9	30·7

Egg vitellin.—Egg yelk was treated with an equal volume of saturated ammonium sulphate solution so as to bring to a state of half saturation. After being allowed to stand for some hours to settle out the precipitate was collected and boiled up with spirit and this process again gone through. Finally, the precipitate was washed with boiling water and subsequently dealt with in the usual way.

Cleavage by potash.	Cleavage by hydrochloric acid.

A third product was obtained from the whites of fresh eggs treated in the same way as the last.

Cleavage by potash.	Cleavage by hydrochloric acid.	
27·2	44·0 48·7	Duplicates.

It will be noted in all these instances that the yield from the acid cleavage is considerably higher than that from the potash. The presumable explanation is contamination with ovomucoid which, as will be subsequently seen, yields much higher figures with the acid than with the potash cleavage. In the first set of instances given ovomucoid would be evidently carried down, as it is precipitable, like albumin, with spirit.

Crystallised ovalbumin.—The whites of fresh eggs were beaten up and mixed with an equal bulk of saturated neutral ammonium sulphate solution. After standing about 12 hours the slight precipitate (globulin) produced was separated by filtration and saturated ammonium sulphate solution was added to the filtrate until a slight permanent precipitate was produced. This was dissolved by the addition of a few drops of water and then one-fifth normal sulphuric acid was pipetted in drop by drop until the solution was just opaque. After 24 hours the crystalline precipitate was filtered off and recrystallised by solution in water and treatment with ammonium sulphate and sulphuric acid. The recrystallised product was dissolved in a large quantity of water, acidified with acetic acid, and coagulated by boiling. The coagulated albumin was collected, washed with boiling water, then with boiling spirit, and afterwards dried and powdered. Two preparations were made and analysed.

(ii.)	23·5 22·5	Duplicates	25·7 24·8	Duplicates.

Conalbumin.—This name has been applied[3] to a form of albumin found in the mother liquid after the separation of the crystallised ovalbumin. It is present in conjunction with ovomucoid. From the filtrate obtained after the removal of the crystallised ovalbumin, the conalbumin and ovomucoid were salted out by the addition of solid ammonium sulphate. On redissolving in water, acidifying, and boiling, the conalbumin was coagulated, whilst the ovomucoid remained in solution. The conalbumin was collected, washed with boiling water, and subsequently with boiling spirit.

Cleavage by potash.		Cleavage by hydrochloric acid.	
26·1 22·1	Duplicates.	34·1 36·9	Duplicates.

Ovomucoid.—The liquid from which the conalbumin had been separated by filtration was evaporated to dryness, whereby the ovomucoid was rendered gelatinous and insoluble in cold water. After repeatedly washing with cold water and boiling with spirit it was collected, dried, and powdered.

Cleavage by potash.	Cleavage by hydrochloric acid.
107·9	215·9

Ovomucoid obtained by another mode of preparation was also dealt with. Dry commercial egg albumin was dissolved in about 15 times its weight of water, acidified, and boiled in order to coagulate the albumin which was removed by filtration. From the clear filtrate [illegible] on the water-bath to a small bulk the [illegible] pitated by the addition of two volumes [illegible] After washing repeatedly with boiling [illegible] ed, dried, an[illegible] powdered.

Osseo- and tendo-mucoid.—In order to ascertain if other mucoids correspond with ovomucoid in the relative results given after cleavage by potash and by acid steps were taken to obtain specimens of osseomucoid and tendomucoid. The process is a tedious and lengthy one but specific directions have been given by Hawk and Gies[4] for osseomucoid and by Cutter and Gies[5] for tendomucoid and these were strictly followed. At first it appeared as if there would be a want of success in obtaining the products but by perseverance in adjusting the acid to the requisite point to produce their precipitation from the half-saturated lime-water extracts that had been previously made and allowing time for the gelatinous form of precipitate produced to settle out the difficulty disappeared. These were the results obtained on subjecting them to the potash and the acid processes of treatment.

[4] American Journal of Physiology, vol. v., 1901.

[5] Ibid., vol. vi., 1901-02.

The same order of figures, it is seen, are observable as for the ovomucoid but the proportionate amounts are less. It may be that this arises from the presence of incidental impurity.

Have we not something in these results which speaks suggestively upon the point of the molecular constitution existing? With ordinary proteids the figures, except in the instances where ovomucoid is liable to be present as an impurity, are practically about the same after the potash and the acid cleavage. This may be expected to be the case if the carbohydrate is present in the proteid molecule in the amylose form. In this form it is simply liberated without being destroyed by the boiling potash and after being hydrolysed by the acid treatment it is estimated as sugar. With the acid cleavage the amylose carbohydrate would at the time of cleavage be hydrolysed into sugar and thus present itself at once in the form of sugar. In the case of the mucoids the figures after the potash cleavage are seen to be conspicuously less than those obtained after cleavage by the acid. The proteid molecule is regarded as consisting of a central intrinsic part with side-chain attachments; and sugar side chains, I think, have been hinted at if they have not been shown to exist. The facts before us seem to me to be suggestive of sugar side chains being present in the case of mucoids. Should they be so they would be acted upon and destroyed by the potash and not by the acid on being cleaved off and thus the smaller potash yield becomes intelligible. After boiling with 2 instead of 10 per cent. potash a much larger yield of carbohydrate is obtained. This appears to arise from some of the mucoid escaping being broken down. Whatever does so would fall like amylose carbohydrate when poured into spirit and on subsequent boiling with the acid cleavage would occur with attendant appearance of sugar.

I have been speaking of the proof afforded, by the agency of chemical breaking down action, of the presence of carbohydrate as a constituent of proteid matter. I will now speak of the information supplied in connexion with this point through quite a different channel and one which bears on action occurring within the living system. Phloridzin, a crystalline principle obtainable from the bark of the stem and root of the cherry and some other allied trees, is known to produce a strongly glycosuric effect when introduced into the system either by the alimentary canal or by intravenous or subcutaneous injection. The glycosuria produced by it differs from the glycosuria arising from other causes in not being due to antecedent hyperglycæmia. In ordinary glycosuric conditions the sugar of the urine is derived from sugar existing in the blood and filtering off with the urine. They are thus associated with hyperglycæmia and this bears a proportionate relation to the sugar elimination. In phloridzin glycosuria, however, no such relationship exists. Indeed, it was said at one time that there was less sugar than normal to be found in the blood. This, as a matter of fact, is not true and the statement depended upon the defective mode of analysis adopted. Some years ago I gave careful attention to the matter and published my results in a communication "On Phloridzin Diabetes" contained in the *Journal of Physiology*.[6] It was there shown that the sugar almost invariably stood somewhat above the normal. I shall revert to this subject in speaking of the mechanism of phloridzin glycosuria and give an explanation of the condition observed.

After intravenous and subcutaneous injections the glycosuria follows very speedily and may be very intense. In one of my experiments the urine contained 112 per 1000 of sugar 2 hours and 25 minutes after a subcutaneous injection. The blood in this case only contained a trifling excess of sugar—a state that could not possibly account for the elimination that occurred. The effect only lasts whilst there is phloridzin present to exert an action, but it may be renewed by a fresh administration. The result occurs in the absence of food. Even after prolonged fasting glycosuria has been found to have been produced. Everything points to the kidney as being the seat not merely of elimination as in other forms of glycosuria but of the production of the sugar and from the work that has been undertaken a relation has been noticed to exist between the nitrogen and sugar discharged. In the fed animal with a store of glycogen in the liver and other parts of the body the sugar is in high and irregular proportion to the nitrogen but by starvation it becomes reduced and is ultimately brought to a constant ratio. At first there is a discharge of the loosely combined carbohydrate existing in the system and whilst this is going on the sugar elimination bears an uncertain relation to that of the nitrogen, but subsequently, when the carbohydrate referred to has been swept away, the two become drawn from proteid disintegration and now the period of fixed relationship is reached. Assuming that this point has been arrived at and that the source of both the sugar and the nitrogen is the disintegrating proteid molecule the relationship between the two ought to afford a basis for calculating the proportionate yield of sugar by it. The nitrogen eliminated corresponds with a given amount of proteid disintegrated. In the dog when the condition is brought to proteid as the only source of the sugar and nitrogen eliminated the relation has been stated to stand at 3·8 of the former to 1 of the latter and upon this relationship the amount of sugar yielded works out at about 60 per cent. of the proteid disintegrated. The ratio of 2·8 to 1 has been more recently asserted[7] to constitute the correct D : N value. Calculating upon this basis the percentage of carbohydrate in proteid stands at about 44 instead of 60. Such is the proposition that has been advanced and it gives a vastly greater carbohydrate component part in the proteid molecule than is given by chemical destructive action. It is evident, however, that the conditions under which cleavage occurs are essentially different in the two cases, seeing that in the one the carbohydrate simply comes straight off, whilst in the other the opportunity exists for the occurrence of intra-molecular action. When carbohydrate enters a molecule rearrangements ensue and it may temporarily assume another grouping. There is abundant evidence to show that carbohydrate may enter a molecule and through re-groupings within may come out in the form of fat, and conversely fat may enter and carbohydrate be split off.

Up to the present I have been looking at the evidence in support of carbohydrate entering into the constitution of proteid from the side of cleavage action. There is another aspect, however, from which the matter may be regarded and this is from the side of construction.

A single instance may be taken to suffice for showing that carbohydrate is susceptible of being built into proteid. Yeast cells may be regarded as little masses of bioplasm and we only know of bioplasm in connexion with proteid as a basis. Placed in a nutrient medium the bioplasm grows and forms fresh bioplasm by incorporating into itself the molecules with which it is adapted to unite. Pasteur showed that yeast cells would grow, which means would form proteid, in a medium consisting of sugar, ammonium tartrate, the ash of yeast, and water. It may reasonably be here inferred that the sugar contributes to the formation of the proteid but no absolute proof of it is afforded seeing that the elements of the sugar—carbon, hydrogen, and oxygen—are also present in the ammonium tartrate. Ammonium nitrate, it has been found, may be substituted for the ammonium tartrate and when this is done the only source for the carbon entering into the constitution of the proteid is from the carbon existing in the sugar. Thus proof is furnished of sugar being turned to account in connexion with the construction of proteid. The other line of evidence adduced showed that carbohydrate, actually as such, enters as a component part into the proteid molecule. In my next lecture I shall deal with the conclusions to be drawn from a review of the knowledge that is now before us.

---

The Vegetarian Congress.—From June 22nd to 24th the International Vegetarian Congress, convened by the Vegetarian Federal Union, was held at the Memorial Hall, Farringdon-street, London, when delegates were present from many parts of the world. Among the matters discussed were diet and physical deterioration, the selection and cooking of vegetables, and the ethical aspect of the movement. On the evening of the opening day a dinner consisting of 15 courses was held at the Holborn Restaurant, the object, apart from its social bearing, being to show the wide scope which vegetables offer for a variety of tasteful and nourishing dishes when combined with eggs, milk, butter, and cheese. On the whole, the tone of many of the speakers during the congress was less aggressive than is usual, but the spirit of antagonism to those who did not hold the same views as themselves was very obvious in some speakers.

The Cavendish Lecture
ON
DISEASE OF THE HEART.

Delivered before the West London Medico-Chirurgical Society on June 23rd, 1905,

By JAMES F. GOODHART, M.D., LL.D. ABERD., F.R.C P. LOND.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL, ETC.

MR. PRESIDENT AND GENTLEMEN,—Destitute as I was when I received the invitation of your council of any idea of a subject in which to interest you for an hour to-night I turned to the titles of some of the former lectures and from them I gathered that all had been strictly clinical in their material and scope and so I determined that mine should be. The one that I have selected, "Disease of the Heart," seems rather a large order, as your secretary remarked, for a short hour but I may at once relieve your minds by saying that this is entirely due to a struggle with my title in which I was mastered and my purpose would, I think, be better expressed if without prejudice I might be allowed to put it in conundrum fashion, When is disease *not* disease? With this aim I shall have to speak of such commonplace subjects as the meaning of what are called functional murmurs, the position of the impulse and its indications, præcordial dulness, such departures from the normal action as intermission, palpitation, tachycardia, and bradycardia, and the bearing of some of these on the diagnosis and treatment of actual disease.

My subject having based itself upon my desire to be on common ground with every one of you I have confined myself almost exclusively to my own observations. I suppose I can hardly be accused of egotism if I assume that I should not have been asked to address a body of experienced men such as are here to-night if it had not been thought that the decades that bring me in sight of artificial teeth and gout waters, face massage, and other devices for postponing age, bring also a right to an opinion of my own, and that this opinion you want to hear. I am but re-telling a well-worn story that others have better told before, but from time to time it needs re-telling, particularly if the opinions are independently your own.

And, first, those murmurs with which I shall concern myself are all systolic. Many are basal, and of these some are over the aortic valves but more over the pulmonary and extending over the right ventricle and towards the apex. Some are loudest in the mitral area and when so they have a tendency, like the basal murmurs, to diffuse themselves in this case upwards round the nipple, to join the basal one, and the two often existing together the one merges into the other and it is difficult indeed to say if there be one murmur or two. Very often, however, there is a purely apical murmur which is heard in a series of separate whiffs or is intensified in whiffs. And these are clearly associated with inspiration. Two or three come in each inspiration as it rises to its acme and then cease again and these may be quite well heard at the angle of the scapula. They are most marked when the patient is nervous under examination and the heart more or less quickened. The murmur most probably *disappears* as the heart quiets down and in all cases it is then much diminished. In similar circumstances there often occur impurities of sound rather than definite murmurs; the first sound loses its cleanness and is converted into a murmurous or humming, or groaning or grunting prolongation, this being confined almost exclusively to the position of the impulse.

Lastly, and perhaps most common of all, there is another murmur, or the same murmur under a different aspect, again systolic and apical, but curving round it upwards towards the base and which has this peculiarity, that it is only brought out by making the patient lie down. The heart sounds, when examined with the patient standing or even sitting, are absolutely healthy, but put the patient on a couch and a more or less well-marked, often quite loud, systolic souffle, in character like that of mitral regurgitation, is developed round the apex. If a somewhat prolonged observation is made it will be found that the murmur varies considerably in intensity at different beats and tends on the whole to disappear after the position assumed has been maintained for some few seconds, or perhaps as much as a minute or two. Much more rarely I have heard a bruit develop when the patient rises, though there has been none when the body was recumbent. Foxwell speaks of this murmur as "the pulmonary murmur" and considers its position to be over the second and third left intercostal spaces. He alludes fully to this characteristic feature of production in the recumbent posture and explains it by stretching of the pulmonary artery under conditions of debility, and he has even known it to develop after the occurrence of heart strain.

If you make a practice of examining the heart of everyone that you see for the first time—no matter what the complaint—both standing up and lying down, I am quite sure that the frequency with which you will find this systolic or these systolic murmurs will surprise you; they are as common as moveable kidneys. These are the chief varieties of what are called "functional" murmurs. I would not say that they are all that occur. They are well known to anyone who has any sufficient opportunities for observation. What, however, is I think not even yet so well known as it ought to be, or allowed for in daily practice, is the *frequency* with which they occur even in healthy subjects, unless mere temporary nervous excitement be judged to be ill-health, and this *variability* in *form* both between one case and another and in the one case also between one moment and another. Their genesis has been discussed repeatedly and still forms a tempting bait in this respect.

Functional murmurs have ever been supposed to convey the indication that at any rate there is something wrong and mostly a blood change to be removed by the administration of iron. At one time or another the site of production has been supposed to be now the aorta; now the pulmonary artery; now the mitral or tricuspid valve; now outside the heart altogether. And he would be a bold man and a very beater of the air who would waste your time by attempting to combat any one of these assertions. At any rate I feel sure that each is true for appropriate cases, but I am concerned to insist that a proportion of them are produced at the mitral orifice; that any one of them may occur in man, woman, boy, or girl, examined, it may be, casually and in whom there need be no sign of any disease or even of disturbance of the action of the heart. I would add as not unimportant to my position that no one of them disappears in any permanent fashion by any means so readily as is perhaps tacitly implied rather than positively asserted.

Now it seems fair to argue that, being so often discovered haphazard, and associated, as they often are, with no symptoms, and being often called into being by a simple change of position of the body, they cannot be, at any rate in many cases, of first-rate importance, and I would venture to change the name of many of them from the old one of "functional" to that of "postural" murmurs. Yet such cases are often rejected at life offices; they are refused for the public services; they come from all quarters committed to the existence of organic heart disease. So common, indeed, are such cases that it is impossible to give even a summary of them, but I will single out a few that have specially interested me or have come across my path while I have been preparing this lecture. A common case is such as this. A tall overgrown nervous youth with a pulse of 104 is under examination. The dulness is decidedly ample over the left side of the chest inside the nipple and there is a diffused forcible impulse spread all over the second, third, fourth, and fifth spaces between the sternum and the left nipple. On auscultation there are a loud systolic murmur over the pulmonary valves, a thick second sound, and at the apex a loud systolic murmur that comes in whiffs as the inspiration rises and disappears absolutely as it wanes. What could sound worse than this description and the case can easily look grave to the examiner, but the signs need all to be seen with the individual as a background and then they are clearly of much less importance. Deduct the nervous excitement and the long narrow chest that cramps the lung and brings the boy's heart unusually to the fore, and then the character of the murmur points to the reasonable probability that the heart is a sound one.

Another case that interested me much at the time was that of a young man, aged 22 years, who, having passed into the Woods and Forests department three years before, was rejected at a final medical examination because he had disease of his heart. He was sent to me by

Mr. H. E. Giffard of Egham, because he could not find anything wrong. I examined his heart in all positions and am sure it was absolutely healthy. I was so convinced that the man must have been nervous under examination and that a mistake had been made that I wrote to the Under Secretary of State and he very kindly acceded at once to my request for a re-examination, but the board adhered to its original opinion and the candidate was again rejected on the ground that he had a valvular murmur that rendered him unfit for service in India. He had never had any trouble with his heart before nor has he had any since, for I heard of him not long ago and I am quite sure there was never anything more than the temporary murmur due to neuro-muscular excitement and I hold that a young man's prospects were unnecessarily placed in jeopardy by reason of ignorance of the character of this murmur.

Another case, a boy, aged nine years, whose father I had seen some years ago as he was dying from cerebral embolism after infective endocarditis, had pneumonia in March, 1904. It was slight and it quite cleared up but his medical attendant at school writes to the medical man at home: "There remains a rather interesting condition of heart or, what I think is quite possible, and more probable, a heart condition that was there before the pneumonia. I find that when lying down the apex beat is outside the nipple line, a distinct murmur can be heard, and the pulse is 80 and irregular. When standing up the apex beat is just inside the nipple line. I cannot hear a murmur and the pulse is 108 and regular. I found that these conditions altered directly he altered his position and however many times one tested." The writer attributes the whole condition to latent rheumatism as the boy had often had pains in his legs and arms and he adds that he had seen similar cases before. Very sagaciously, however, he did not commit himself in any way to the mother of the boy but passed on his impressions to the home medical man for further observation, whose subsequent remarks are equally pertinent. He notes that "when lying down the irregularity of action, as well as the loudness of the murmur, altered when the boy held his breath for a few seconds, the action being much steadier and the murmur less marked. There is nothing abnormal discoverable when he is standing up, even after exertion, such as running round the room twice. The beat is in the normal position and the action quite steady." "The interesting question is," says the medical man, "as to this being a temporary condition which the boy will grow out of; he has grown very rapidly of late. I have advised the mother not to allow the boy to bicycle or undergo any severe exertion for as long as there is a doubt if the condition be permanent or temporary, it being as well to be on the safe side." Advice, I may add, lest it should seem to any to be in excess of the demand, that I thoroughly endorse.[1]

Here is another case that is more doubtful and I give it especially because it is so, for I by no means wish to convey that all of them are free from difficulty. Many want watching and hasty opinions are always bad practice. The patient was a youth, aged 16 years, in whom a murmur had been noticed at the apex two years before I saw him, with some displacement of the impulse beyond the nipple line. It was first noticed after a five mile run. He had been carefully looked after and allowed to bicycle and to cricket a little, and he was much better than he had been; indeed, I think his parents thought too much was being made of his ailment, as they could not see that the boy was in any way incapacitated. But he wanted to go into the army and what were his chances of passing the medical examination became an important question. When lying down there was a systolic murmur, audible from the third rib to the left of the sternum, downwards by the side of that bone, curving round in the fifth space, and below the nipple up into the axilla, where it became much softer. When standing it became both variable in position and intensity. The impulse was forcible and diffused. I do not think this boy will pass into the army and I certainly should not quarrel with anyone for refusing him, or even if anyone were to say the heart were dilated, though I do not think it is; on the contrary, I believe the heart will prove a serviceable and a sound one as the framework of the boy's chest develops.

Once more, I saw last June a man in the army, aged 21 years. He had been sent home from India with this history. He was about to be placed under an anæsthetic for abscess in his foot and an examination of the heart showed the impulse in the normal position, but also in the epigastrium and over the right ventricle. The first sound was accentuated and was accompanied by a blowing systolic murmur over the tricuspid area. The remark appended is that the local signs are in favour of an organic lesion, but the improvement of the man's general health pointed to a functional murmur. I saw him with his then medical man a month or so after he arrived home and his symptoms were chiefly a rapid nervous action. I cannot now say if there was any murmur, but I considered it essentially a nervous heart, and that there was no occasion to be anxious about his future. We lost sight of him and he eventually went out to India again after six months' leave, and as soon as he started work and long and heavy marches he broke down again from, as he told me when I pressed him for definite symptoms, sheer exhaustion. And he was sent home "suffering from *valvular disease*, the effect of climate and duty," the *physical signs*, as recorded on his health sheet, being taken to indicate "organic mitral regurgitation with tricuspid insufficiency." But what do I find? When standing there is absolutely no abnormality of any kind. When recumbent the heart's action becomes cantering and there is an impurity of sounds both at the apex and the base. The real explanation of the case is that he has never as yet had the stamina required for the army, and under the stress of climate and duty he becomes played out not in the heart more than any other muscle, and as soon as he is off duty he recovers himself as he did on the former occasion.

Many a difficulty is there with these cases, and I cannot too strongly urge the necessity of taking a more liberal view of the power of disappearance of even well marked cardiac murmurs. There is no need to neglect them or even to make unduly light of them. We do not know and must wait and see. Such cases need watching and examining from time to time. It is easy to do this without committing one's self to any irrevocable diagnosis or prognosis until time has shown the way. And perhaps this applies with more especial force to childhood than to adult life. Pyrexial disturbances of all sorts are of the commonest of maladies up to ten or 12 years, and there is nothing more common during these attacks than for the first sound of the heart to develop a systolic murmur, in association with the excitement of the muscular action that is one of the common phenomena of fever. Clearly the heart in such cases requires to be kept under careful observation, lest anything escape us of permanent import to the integrity of the organ, but there is no need to excite the apprehensions of the parents. It is a feature of the febrile reaction of childhood and for the most part these bruits quite disappear as the fever subsides and the child recovers tone. In so important a matter as the question of the existence of endocarditis or valvular disease no one should precipitately commit himself to an opinion from which it will be difficult to extricate either himself or his patient. Let me illustrate this by a case. A child has had an attack of fever. A systolic murmur has developed and the heart is said to be affected, and the future sketched out in somewhat sombre light. The fat is all in the fire from the mention of heart disease and the necessity for prolonged rest. But the child was not ill, the temperature was not yet stable, and although admittedly there was a systolic murmur audible from time to time, and I think some little displacement of the impulse, I took a much more sanguine view, based upon the grounds I have already given, that the murmur was a variable one, being frequently entirely absent, and that it was also distinctly a postural one. But it was obvious that my opinion was neither expected nor acquiesced in and I should not be surprised if that child were still undergoing the harmful process of being shielded from his environment in every possible way because he labours under the suspicion of having disease of the heart.

From the question of murmurs I pass to the impulse of the heart or the position of the apex beat as it is more generally called and its meanings or indications. Upon this also far too much stress is laid as an indication of disease. The impulse has been described as having certain relations to the nipple and the fifth space, and I am far from attempting or wishing to question such a rudimentary fact, but it does not follow that if there be a departure from the normal in this respect it is so much the worse for the subject of the deviation. It is possible to live a healthy life with the apex beat outside the nipple and much more often so than some would seem to suppose. Why not? The heart is free to move within a considerable radius upon its suspensory ligaments at its base and we are dealing with the living nervous heart, with the heart in action, and there is much need for caution in forming conclusions with respect to an organ of this sort. The position of the heart's impulse depends in truth a good deal in the individual upon the shape of the chest, upon the condition of the lung, upon the rate of action of the heart, whether hurried or not, and it depends upon the true concurrence of the systole of the many individual muscle bundles that the heart contains. Thus, in small and long-chested people the heart is *likely* to be outside its normal limit and yet have no ill-meaning such as we are discussing. So, also, in those who expand their lungs badly, or who are nervous under examination, the impulse may be considerably outside the nipple line. I saw a child not so long ago in whom, although the heart was beating an inch beyond this limit, I could not find the slightest evidence of any disease. The child had been said to have heart disease but surely in the absence of all other evidence it was better to let the child live a healthy life and watch than to condemn it for one sign such as this. I think it is of some importance to insist that this concurrence of the muscle bundles in their systolic contraction is by no means habitually so perfect as we are in the habit of assuming. I cannot help thinking that temporary reflux at the mitral orifice is not uncommon from some such cause and that we are too much inclined to ascribe it to disease. We think of the systole as a sudden solid contraction of all the muscle of the ventricular wall, but observation and experience alike show that the departures from this precise action are by no means few and far between. Take the passing irregularities that come to so many after a meal, after drinking tea, after smoking, excitement, or fatigue. They are, of course, exceedingly common and when we watch the impulse in such we certainly find it now here, now there. It is clearly due to some want of synchronism in the individual fasciculi and it is not necessarily a matter of vital importance, although it is certainly one of physiological interest.

---

[1] I am indebted to Dr. J. G. McLaunahan of Stonehouse, under whom this boy came at a subsequent period, for permission to make use of these notes.

Nor must I omit to say a word upon the value of dulness. Within limits rather jealously watched I should regard it as a safer sign of disease than the position of the impulse. But these limits must not be unduly stretched at the bidding of bias. Everyone knows that great increase of the size of the heart may be present without any increase of the dulness and, on the other hand, and it is with this that I am more concerned, there may be apparent increase of dulness without any increase of the size of the heart or of its cavities. Increase of the natural præcordial dulness often means no more than an altered relation of the heart to the chest wall or surface; a change in the pulmonary circulation or inflation and not in the heart itself. For example, in narrow-chested people of all ages and either sex, although women and children are its best illustrants, the dulness is often large from the simple fact that the lungs are small and not fully inflated and therefore the heart is much more extensively in contact with the chest wall in front; and under this condition in a nervous subject, to hark back to the former section, it is wonderful how masterful the beat seems to be, and there is indeed excuse for thinking the organ diseased, although it is in truth quite healthy. But then as regards dulness, I would have these remarks apply chiefly to dulness at the base and over the right side and very cautiously indeed, if at all, to the region of the apex. And obviously because the apex of the heart is covered in more or less by lung; lung and stomach tend to tilt it round and away at this part, as it lies trending from the surface. So that, as I have said, there may be a very large heart that is undiscoverable by percussion and a natural heart that may yet appear large. Even the spleen and the left lobe of the liver will get in the way of the determination of the position of the heart towards the apex; and as a result of long-continued observation I must say that I regard percussion in this region as of but little use and liable, if we depend upon it much, to lead to serious errors. I therefore find it impossible to agree with the conclusions of those who when they detect small differences in this area after baths and other forms of treatment ascribe it to a reduction in the size of the heart. It seems to me that the Nauheim treatment in appropriate cases—not all and sundry—has indeed the warranty of *results* but not that of any convincing topographical argument such as its advocates claim for it.

I come next to a number of cardiac disturbances which group themselves together under irregularities of action, and as an introduction to the subject I can hardly do better than recall to your minds all the vagaries of the action of the muscular fibre of the heart that you may hear in any one afternoon in the out-patient room under the excitement of examination. The noises, the plunges, the thuds, the sudden momentary stops that come; and have you not often wished, as I have done, when, as sometimes happens, the case staggers experience, and when, as I maintain, it is a more vital matter to be able to say positively that there is *no* disease than to say there *is*, for the happiness of a life is far more linked to the verdict, "You are *healthy*," than to that other, "You are not quite sound, and you must take care of yourself," for the one means a full life and the other a maimed one; have you never wished, I say, that some mechanical genius would invent such a cardiaphone as would enable one to examine that heart as its subject slept, untrammelled by his nerves? Any of these conditions may be evidence of serious organic disease and a breakdown in the near future, but in themselves they may be simple functional disturbances and of no great moment. Taken as they come I think it is not untrue to say that they may be regarded as trivial, or at any rate hopefully, until you have proved them to be otherwise. This applies to some more than to others. Bradycardia and pain are certainly the most ominous but either may be temporary only. Tachycardia in like manner is often a mere nerve excitement and of no importance, though in certain circumstances it is a most dangerous disease.

Let me say a few words about each of these separatel and perhaps as most common comes first an irregular intermitting heart. I know not which is the more commo or the less important. A heart that beats irregularly i time is very common as a transient thing. Again I ma advert to the power of the mere change of position of th body to effect this. Put a man on his back, from th erect position, and it will happen very often that th heart changes at once from a steady beat to a cantering or galloping action, or some new rhythm ma develop, such as two beats distinct, followed by tw feebler beats, or a more generally patternless irregularit may ensue. Those past middle age furnish the best examples at once of cardiac irregularity and of the difficult there is in judging of its value as a symptom. There is, of course, an irregularity that is associated with definite signs of defect, either muscular or valvular, and symptoms of failure in the circulation. I do not allude to that. The picture that comes before me is that of the man or woman of, say, from 45 to 60 years or more, who suddenly, perhaps, becomes conscious of a frequent full or choking sensation at the top of the sternum, or of indigestion. You examine and find the heart pirouetting behind the chest wall like a ballet dancer or a performance on the bagpipes to the tune of a Highland reel, if you could convert the idea of sound into that of motion. Such a condition as this has a special proneness to come on after food when the stomach is distended, or later when there is a tendency for the irregularity or intermission to be attended by the eructation of gas. It is clear that these conditions are often enough no matter of disease, for the attacks come on from time to time; they come and go quite suddenly; are absent often for weeks or months; between times there is no shortness of breath or other evidence of heart disturbance; and they are likely to be associated with the presence of uric acid in the urine There is plenty of evidence, therefore, that some fault of metabolism exists and therefore some temporary changes in the nutritive fluids. One may well doubt if several causes, each in its own degree, may not conduce to this overcharging of the furnaces, but so marked is the association with one or other stage of digestion that I cannot but think that many own immediately an abdominal origin; that they are caused through some waning influence on the part of the great ganglia of the abdominal nervous system. And perhaps this may throw some small ray of light upon one or two other maladies which, although we must call them disease, it is questionable whether *quâ* heart they are really so. Two are common; two are of pathetic interest, so swift, so tragic, is their ending. I will take them in their order—Graves's disease, angina pectoris, some forms of sudden death.

The first named comes properly next, as in effect it is a similar malady to that just described. It differs in no other way than that it is much more likely to be intractable and even permanent in some. No better illustration of the need for keeping separate disease and unnatural function could be given, for it will exist for years without producing evidence of disease and it therefore affords the best possible example of the never-say-die principle that is inherent in the heart and of the power of that organ to cope, and to cope successfully, with very adverse circumstances. Angina pectoris is not as happy in this respect, but it also has in some respects a similar history. It is well known that when anyone dies from this malady the coronary arteries are almost invariably found diseased, and although it has been a much vexed question the changes found have come to be considered as its cause. And I think Osler at any rate has stated that in *most* cases carefully examined during life some evidence of disease about the aorta will be found to exist. I demur to both opinions. Angina pectoris is common amongst us, if we are on the look out for the milder forms of it, but then it is not for me a sudden dreadful chest pang that comes and kills within, perhaps, a few hours. That is a rare variety. It is much more a paroxysmal twinge in the epigastrium or chest that almost invariably takes a man in walking, and apparently because he walks and because he walks up-hill, and moreover it is quite astonishing at how small an incline the anginal patient will shy. He stops and looks into a shop and within a few seconds the pain will have vanished and its departure is nearly always associated with the eructation of wind. So much is this the case that it is often mistaken for a simple indigestion, which is all the more plausible in that it is a common visitant when the walk is taken soon after a meal. It is constantly finding out the City man after his breakfast. It is also a malady that comes and goes, sometimes goes altogether, but is also more usually one of the most intractable of the neuralgiæ with which we are called upon to deal, and too often it has come to stay with intermissions. And here is the point: I have known it to last in two cases 20 years, and several times some, if not many, years, so long indeed that it seems impossible, at least unlikely, that the disease which was found at the last was indeed present at first. I have certainly examined these mild cases by the score without finding any trace of disease of the heart and all my later experience confirms me in saying what I said years ago in this respect, that the pain is best explained by regarding it as a neuralgia, or storm, that emanates from the great abdominal brain, although I was inclined at one time to regard it as a cramp of the heart.

It might perhaps be thought that the very generally accepted association of vascular tension with angina is adverse to this opinion and so I think it might be. But I have never yet accepted this view of angina pectoris for more than a small proportion of cases. I say—assured in my own mind that I am right, although it is contrary to the opinion of the most experienced men—that, as a rule, there is no increase of tension; I have had my finger on the pulse all through a spasm of angina many a time. Angina is if anything a disease of low tension, as is to be expected of a crushing pain that emanates from the pit of the stomach. A man is seized in the graver cases with a pain so bad that it kills him. He knows that he is dying and he dies—a quite uncommon fact in human experience—and we call it heart disease. Why? for my very life I cannot imagine. These are not the symptoms of heart disease. The symptoms of heart disease are mechanical, plus distress, not *agony*. And, moreover, the most extreme arterial tension may be quite free from pain. Or in the commoner cases perhaps the man goes to bed, wakes up with a pain—how bad can be never told—and he dies quite quietly. A sudden death from heart disease again we call it; but the untutored juryman in such a case comes nearer the mark, I fancy, when he returns his verdict as the "visitation of God," for is not the catastrophe much more like a lightning stroke that has rent the organism, stopped the machinery, and left no trace of the real cause behind it?

Of the usual explanation of sudden death when no obvious cause exists I have much the same to say. Such cases are not common, but they occur, and heart failure is now the prevailing diagnosis, I think; it occurs so often in the first columns of the *Times*. But I refuse to accept such a verdict when, as is surely no uncommon occurrence, the accused organ has been examined within quite recent times and to all outward seeming has been passed as healthy. Moreover, the heart has far too much grit in it to tumble down dead except under well-known and definite conditions.

Not much time remains to me to discuss the other two muscular derangements which I have included in my list—viz., tachycardia and bradycardia, or the runaway heart and the slow heart. The runaway heart we are in the habit of considering as a *nerve* effect—that is, as some disturbance of the regulating ganglion of the heart; but I doubt if this be so for the slow heart, in which there is at any rate a common tendency to assume degenerative changes in the muscular wall with all the necessary consequences. Yet the evidence is not wanting in many of these cases as the fault runs on that points the other way. One can readily understand that if the nervous energy of the heart should fail the muscle would probably lose its tone and dilatation of the wall would be very likely to follow. But that there is any appreciable change either in nerve or muscle in the first instance is surely disproved by its suddenness of onset, and sometimes (probably generally in the case of tachycardia) of its departure, good health remaining between whiles. I should not say that a preternaturally slow pulse was often sudden in its subsidence, although I have known it so, and perhaps especially in cases that have raised suspicions of gout. As a rule it occurs in people past 50 years of age, and when it comes it comes to stay. But there need be no symptoms of heart failure; it would seem more as if the generator were working badly, and by-and-by a switch fails, the circuit breaks, and dissolution comes. I incline towards some of such cases at any rate being bulbar in their origin. And as bearing on this point think of the heart, the pulse, of Addison's disease; the heart, the pulse, of severe abdominal injuries, and of other maladies I cannot now mention. The heart you can hardly hear, the pulse you can hardly feel, and yet withal a something about them quite different from the "weak" heart, the "weak" pulse of common parlance, which mean nothing at all. There can be no question of disease of the heart in these; they are suffering from a profound interference with the great nervous centres of animal life; the pitcher is broken at the fountain, and you know it, but yet it is past finding out. All these muscular anomalies, too often ascribed to fatty and other degenerative changes in the wall of the heart itself, link up together in one great group, whether they be slow hearts or quick hearts, or irregular hearts, or what not. They are all more or less an expression of, if you like, morbid, nervous agency, of which some perhaps are toxic and temporary, some neuritic and likely to be permanent.

Now I wonder whether you have followed my drift, for I must confess as I retrace my own thought that innocence and guilt seem to have been somewhat incongruously mixed; I must often have seemed to have been straining at a gnat and swallowing a camel. Nevertheless, this endeavour to bring within proper limits, and only this, the significance of some of the common forms of departure from the normal function of the heart is directed to the diagnosis, treatment, and prevention of real disease. Discussing a questionable case of heart disease the other day it was said to me: "There is no *disease*; the heart is only a little dilated and fatty." But what more disease can you ask? It points well my moral, which is this: that all these ailments which I have mentioned, ofttimes trivial, ofttimes transient, are too often but pegs upon which to hang a diagnosis of dilatation of the heart, and in the present day we make much too free use of this diagnosis. I regard dilatation as one of the worst of all the heart's diseases and to play with such a term is to play with a torpedo. Surely dilatation, save in exceptional circumstances, should be reserved for a disease that is associated with some series of definite symptoms, not made dependent, as over and over again it has been, upon the mere fact that the impulse can be felt to beat in the nipple line or even, perhaps a little beyond it, or some transient murmur has made its appearance. I must not go so far as to say that dilatation cannot exist without symptoms, for in the obscurity that surrounds sudden death it may be that it can; still it must surely be an exceptional occurrence and I think one ought to expect that even in slight degrees some of the signs of a failing circulation should exist and amongst these I emphatically do *not* include either giddiness or fainting. Disease of the heart seldom, if ever, causes either. I have often said this before but it is a point that still needs rubbing in.

If ever the history of medicine for this last decade or two should come to receive any exhaustive description I fancy that upon the Nauheim treatment for dilatation of the heart will rest a large share of responsibility in this matter for dwelling with such insistence upon the existence of dilatation when signs and symptoms other than dulness on percussion are completely, or almost so, in abeyance. The weaklings and sensitive about their health, always anxious about "the weak heart," have caught on, so to speak, and numbers have flocked to this place and to that for baths and exercises for the minor ailments which I have indicated who have been quite free from anything like dilatation and from any real disease. And the general trend on the part of the delicate has, I think, reacted upon us, and in our dread lest we make a mistake we have too often outrun all sobriety of judgment. And why do I make such a point of this? Because as I think it is a harmful thing for anyone to coddle his heart when there is no disease, and I think we are far too instrumental in aiding and abetting this. As regards dilatation I rather hope I see signs of a turn in the tide, for on two occasions of late patients have said to me spontaneously that they have got a distended, not a dilated, heart, and perhaps that was so. But there are other terms in general use that I like little better than this one of dilatation because they have come to mean too much. One of them is heart strain. Take the last case of this kind that has come before me. A young man, aged 25 years, has strained his heart, so he says, rowing three years ago, and has never been well since, his heart still running away if he does anything violent. But what is the truth about him? He is a six feet four inches specimen of the most weedy nervous humanity one could ask to see, with a spine like a corkscrew and lungs of course to match. His weight is only 10 stones 12 pounds. His heart is sound enough. It is no fair description to call this heart strain; lung strain would be more to the point if one needed to single out an organ; but a neglected sapling would better describe him. He is chained to a desk from ten to four, has three weeks' holiday once a year, and at night is a tag of the fringe of a great city. What is there of fitness in calling this disease of the heart? or heart strain? At any rate, if it be, the treatment for it, if it could be adopted, would be to send him rough-riding over a cattle ranch for a year or two to develop his muscular and bony frame—that is, more work for his heart and not less.

We must all have come across many similar cases, some even may be who have been condemned to long periods of inactivity because of one or other of these several conditions I have mentioned. But I doubt if rest is the proper treatment for such cases or if the heart should in any case be the subject of blame. My conviction is that if nothing were said about the heart, the patient calmed, kept quiet for a day or two, and then allowed gradually to resume his natural pursuits we should have far less of the months of cardiac trouble that are now, as I think, by no means uncommon.

A weak heart has served me as a text before now but it still flourishes as strong as, if not stronger than, ever. I should have no objection to the term if it were one devoted exclusively to letting down easily the man with real disease and of keeping life and hope within him. Such a use would, to my mind, be nothing but good and proper, but it is a very different matter when its chief purpose is to clothe a sound heart in the garb of a diseased one. A man with aortic regurgitation the other day wanted me to call his heart a weak one, and as I had already told him that he had a definite valvular defect I was willing to fall in with his humour, and to agree with him that his heart *was* decidedly "*weak!*" No harm was done there, but I by no means feel so accommodating when I am asked to call a heart weak when after careful examination I have found it healthy. I only know of two kinds of heart, the healthy and the diseased ones, and these weak hearts, like the dilated ones that I come across, are nearly always structurally sound. What are the symptoms of a weak heart? I know of none. And yet the use of the term leads either to a state of nervous dread, from which recovery is most difficult, or else to a life of luxurious idleness, which, by the enervation it causes, is likely sooner or later to be precedent to the end it would seek to avoid.

I cannot help thinking that in this day of what we must do and what we may not do, this abundant care for the well-being of the individual in all directions, we are getting somewhat sickly in our views of health, and we are in danger of assuming the existence of a tripe-like heart, and overlooking the energetic attributes of living muscle? The heart does not become dilated readily. On the contrary, it is equal, and more than equal, to all the ordinary, and many of the extraordinary, emergencies of life. Ay, and I am glad to insist upon much more than that, for, as you all well know, even under the stress of serious incurable disease its energy will keep its failing powers going for much longer than our poor forecast gives it credit and that sometimes it is all the better for being so called upon. I cannot give a better illustration of this than the case of mitral stenosis.

When we consider that nearly always the contraction of the valve must take years to mature and even when it is apparently fully come it may last, as I can say, for 20 years, the subject even living a fairly active and useful life, one may well carry the lesson to other forms of heart disease and deal a little less extravagantly with the principle of rest. I often see, as I think, this treatment pushed too far, or perhaps I ought rather to say that judging no man I often ask myself, Is this good or bad treatment? I see people absolutely forbidden to walk up hill or exercised—no, aired only—in a bath chair, or carried up and down stairs, or pinned to bed, and I feel inclined, with the world, the flesh, and the Devil of my earlier years, to renounce them all. I daresay I am wrong, but it is seldom indeed that I order anyone to be carried upstairs. It should be reserved for well considered emergencies that seldom come, and Oertel's suggestion of graduated exercise up hill I believe to be a most valuable one, provided that it is taken very slowly and with the mouth open. In this frame of mind one will make mistakes. I sadly and sorrowfully admit it. Indeed, in the mood of the great Napoleon, I must say I have been mistaken so often I no longer blush for it and, no doubt, after having given a positive opinion in favour of a sound heart a sudden death will now and again come to torture you and as it were to make you hesitate in the course marked out. Such things may well quicken our perception and go to render our judgment more keen. But none the less I am sure of this, that we do far more good in our day by pronouncing people sound, if out of health, and by sending them forth with strengthened hope, than by keeping them in the chains of uncertainty and nervous dread, than which nothing can be more crushing to the utility of a life or more harmful to the chance of regaining health.

Years ago there was a discussion at one of the societies upon aneurysm of the aortic arch, and I, having made the remark that it was practically an incurable disease, as judged from the evidence of the post-mortem room and the museums, and so it is, Sir William Broadbent promptly and felicitously retorted that the post-mortem room was not the place to look for cures! I was quick to see then that what seemed an obvious truism did but dissemble the truth, but to-day and here I am older, and I now see that other face with fuller meaning, which then perhaps I slighted. And so I have availed myself of the honour you have done me to discourse to-night in other terms upon the buoyancy of life and to preach that it is not well to seek too much for the dead amongst the living. To ask you to accept my opinions would be the last thing that I would do but I may ask you to think them over and weld anything that may be agreeable thereto with your own experience.

THE REACTION OF PHENYLHYDRAZIN WITH OTHER SUBSTANCES THAN DEXTROSE OCCURRING IN THE URINE.[1]

BY P. J. CAMMIDGE, M.B. LOND., D.P.H. CANTAB., &C.

THE application of phenylhydrazin as a reagent for th detection of sugar in the urine marked an epoch in the investigation of glycosuria and allied conditions; for not onl is it much more delicate than any test previously employed but it is unaffected by other substances such as creatin creatinin, hippuric acid, homogentisic acid, and excess o uric acid or urates, as met with in human urine, that ar liable to give rise to difficulties when most other method of detecting sugar are relied upon. This reagent has als the advantage of allowing the various forms of carbohydrate to be distinguished. This is a matter of som importance, for although dextrose is undoubtedly the commonest sugar met with in the urine, there is considerabl evidence to show that other forms of carbohydrate an allied substances occur more frequently than has been supposed and that their presence is associated with various abnormalities of metabolism. As more detailed attention is paid to the investigation of the urine in cases of supposed diabetes and some diseases in which glycosuria is likely to occur, our knowledge of the true significance of these rarer forms will be increased and possibly at the same time our information as to the mechanism of normal carbohydrate metabolism may also be added to. A brief survey of the more important characters of the phenylhydrazin compounds which may be derived from the urine may be of some service. The test is now frequently employed clinically, but it is not often that the investigation is carried further than the preparation of the osazone crystals and it is probable that much valuable information is missed in consequence.

---

[1] A paper read before the Royal Medical and Chirurgical Society o June 6th, 1905.

The method of performing the phenylhydrazin test described by von Jaksch has been much modified by subsequent writers and, since the physical conditions under which it is carried out materially affect the result, it will be necessary to refer to the chief variations proposed. Von Jaksch originally recommended[2] that 50 cubic centimetres of the urine to be tested should be mixed with two grammes of sodium acetate and from one to two grammes of phenylhydrazin hydrochloride, and that the mixture be heated in a water bath for from 20 minutes to half an hour. If glucose is present the osazone then separates out on cooling as an amorphous or crystalline deposit of a yellow or reddish colour. If amorphous, the precipitate can be recovered in a crystalline form by dissolving it in hot alcohol, diluting the solution with water, boiling to expel the alcohol and then cooling. This method of performing the test takes time and requires the use of special apparatus which is not always available. To obviate these difficulties and render the reaction convenient for clinical use it has been suggested[3] that 0·5 gramme of phenylhydrazin hydrochloride and 1·5 grammes of sodium acetate should be dissolved by gentle heat in a few cubic centimetres of water in a test-tube and then 5 to 10 cubic centimetres of the urine added. The mixture is brought to the boiling point and maintained there for three minutes with strong and five minutes with weak solutions of sugar. The test-tube is then set aside to cool and the deposit examined for osazone crystals in five or ten minutes. Some authorities, following E. Fischer,[4] have preferred to use phenylhydrazin and not the hydrochloride but it has the disadvantage of not keeping well. A knife-point of sodium acetate is added to 10 cubic centimetres of the urine, then from one to two cubic centimetres of 10 per cent. acetic acid, and five drops of pure phenylhydrazin introduced. The mixture is heated in the water bath or over the free flame in the same way as when the hydrochloride is employed. A recent modification of this method suggested by Kowarski,[5] which gives very satisfactory results and is more delicate, consists in mixing five drops of pure phenylhydrazin in a test-tube with ten drops of acetic acid, gently shaking and then adding about one cubic centimetre of a saturated solution of sodium chloride. To the solid mass that forms are added from three to five cubic centimetres of the urine and the test-tube is heated in the free flame for two minutes after its contents begin to boil. On cooling the osazone crystals separate from urines containing over 0·2 per cent. of sugar in one minute and from weaker solutions in about five minutes.

In whichever way the test is carried out a difficulty occasionally arises from the formation of a crystalline phenylhydrazin compound of glycuronic acid which is liable to be mistaken for the osazone of a sugar It has been stated[6] that prolonged heating tends to obviate this source of error, the glycuronic acid compound being precipitated on cooling as a brown amorphous mass and not in the crystalline form. In the examination of 100 normal urines I sought to test the truth of this statement and found that when heated in the water bath for an hour four of them showed a crystalline deposit, while by boiling in the free flame for five minutes six specimens gave a positive result. Using the same methods but shortening the period of heating to 20 minutes and two minutes respectively exactly the same results were obtained, so that the mere time or method of applying the heat cannot be relied upon to differentiate glycuronic acid from the sugars. In addition to dextrose, the sugars lævulose, lactose, maltose, isomaltose, and the pentoses, arabinose and xylose, have been described as occurring in the urine and forming compounds with phenylhydrazin. Glycuronic acid, as I have already mentioned, also forms a compound with this substance and exceptionally combinations with acetone, aceto-acetic acid, oxalic acid, and in very concentrated urines with uric acid may also be encountered. As human urine is relatively poor in uric acid, the last named does not call for further remark. The acetone compound occurs as needles which melt to oily globules at 16° C., while the oxalic acid salt separates as insoluble, glancing, colourless plates which melt at from 172 to 173° C. The phenylhydrazin compounds of the remaining substances possess certain physical and chemical characters by which they can be more or less readily differentiated. The chief of these are: (1) the rate of osazone formation; (2) the microscopical characters of the crystals; (3) the solubilities of the osazones in various reagents; (4) the melting points of the purified products; and (5) the percentage content of nitrogen.

1. The rate of osazone formation is a point of considerable importance in determining the variety of sugar present in a particular solution, for, as Marquenne has shown,[7] this is a property which has very characteristic variations for the different carbohydrates. Under experimental conditions, with solutions of definite strength, exact time-limits for the appearance of the osazone can be laid down. Although this is not feasible with such a liquid as urine, where the proportion of sugar present is unknown, valuable information can be obtained by observing the conditions and rate of osazone formation. The compound formed by dextrose and lævulose separates from the hot solution after a comparatively brief interval, the former in most cases with characteristic suddenness. The osazones of maltose, lactose, and the pentoses only form after much more prolonged heating and although crystals of pentosazone may eventually separate from the hot solution, maltosazone and lactosazone never appear until the fluid cools, no matter how long it may be boiled. In my experience the rapid method of performing the phenylhydrazin test gives a reaction with all sugar when ten cubic centimetres of the urine are used and the heating is continued for at least five minutes. In the water bath, however, even an hour is not sufficient to obtain a satisfactory yield with maltose, lactose, and pentose, an hour and a half or even two hours being required to demonstrate their presence satisfactorily, especially when the solution is weak. Those who prefer to use the water-bath method, therefore, and limit its time of application to 15 or 30 minutes can only expect to demonstrate dextrose or the more readily precipitated sugars and possibly also any glycuronic acid compounds that may be present in the urine.

2. Microscopical examination of the crystalline deposit obtained after treatment with phenylhydrazin shows certain differences in the characters, size, and arrangement of the crystals which are suggestive. The large yellow needles arranged in sheaves and rosettes yielded by dextrose are well known. Lævulosazone resembles glucosazone, but there is less tendency to rosette formation and the crystals are usually somewhat longer and more slender. Lactosazone occurs as spherical masses of crystals resembling a shaggy yellow chrysanthemum. At the periphery the separate crystals can be distinguished and are seen to be slender, flexible, and hair-like, but in the centre they are felted together into a brown semi-opaque mass. In preparations made by the rapid method the individual crystals are usually not as distinct as those formed after prolonged heating in the water-bath, the appearance presented being that of a brown central boss surrounded by a light yellow halo showing "fine" radial striations. The crystals of maltosazone are short, stiff, and sword like, and are arranged in small rosettes when prepared by the water-bath method. Preparations made by heating in the free flame are less characteristic, consisting of narrow crystals grouped in small bushy sheaves. Isomaltose yields masses of aggregated flexible needles of a golden-yellow colour, mostly arranged in spheres. The pentose crystals are silky, tangled, curved needles, generally arranged in rosettes. The shape, size, and arrangement of the crystals are influenced to a certain extent by the

on percussion are completely, or almost so, in abeyance. The weaklings and sensitive about their health, always anxious about "the weak heart," have caught on, so to speak, and numbers have flocked to this place and to that for baths and exercises for the minor ailments which I have indicated who have been quite free from anything like dilatation and from any real disease. And the general trend on the part of the delicate has, I think, reacted upon us, and in our dread lest we make a mistake we have too often outrun all sobriety of judgment. And why do I make such a point of this? Because as I think it is a harmful thing for anyone to coddle his heart when there is no disease, and *I think* we are *far too instrumental in aiding* and abetting this. As regards dilatation I rather hope I see signs of a turn in the tide, for on two occasions of late patients have said to me spontaneously that they have got a distended, not a dilated, heart, and perhaps that was so. But there are other terms in general use that I like little better than this one of dilatation because they have come to mean too much. One of them is heart strain. Take the last case of this kind that has come before me. A young man, aged 25 years, has strained *his heart, so he says, rowing* three years ago, and has never been well since, his heart still running away if he does anything violent. But what is the truth about him? He is a six feet four inches specimen of the most weedy nervous humanity one could ask to see, with a spine like a corkscrew and lungs of course to match. His weight is only 10 stones 12 pounds. His heart is sound enough. It is no fair *description to call this heart strain*; lung strain would be more to the point if one needed to single out an organ; but a neglected sapling would better describe him. He is chained to a desk from ten to four, has three weeks' *holiday* once a year, and at night is a tag of the fringe of a great city. What is there of fitness in calling this disease of the heart? or heart strain? At any rate, if it be, the treatment for it, if it could be adopted, would be to send him rough-riding over a cattle ranch for a year or two to develop his muscular and bony frame—that is, more work for his heart and not less.

We must all have come across many similar cases, some even may be who have been condemned to long periods of inactivity because of one or other of these several conditions *I have mentioned.* But I doubt if rest is the proper treatment for such cases or if the heart should in any case be the subject of blame. My conviction is that if nothing were said about the heart, the patient calmed, kept quiet for a day or two, and then allowed gradually to resume his natural pursuits we should have far less of the months of cardiac trouble that are now, as I think, by no means *uncommon.*

A weak heart has served me as a text before now but it still flourishes as strong as, if not stronger than, ever. I should have no objection to the term if it were one devoted exclusively to letting down easily the man with real disease and of keeping life and hope within *him.* Such a use would, to my mind, be nothing but good and proper, but it is a very different matter when its chief purpose *is to clothe* a sound heart in the garb of a diseased *one.* A man with aortic regurgitation the other day wanted me to call his heart a weak one, and as I had already told him that he had a definite valvular defect I was willing to fall in with his humour, and to agree with *him that his* heart *was* decidedly "*weak!*" No harm was done there, but I by no means feel *so accommodating* when I am asked *to call a heart* weak when after careful examination I have found it healthy. I only know of two kinds of heart, the healthy and the diseased *ones*, and *these* weak hearts, like the dilated ones that I come across, are nearly always structurally sound. What are the *symptoms of a weak heart?* I know of none. And yet the use of the term leads either to a state of nervous dread, from which recovery is most difficult, or else to a life of luxurious idleness, which, by the enervation *it causes, is* likely sooner or later to be precedent to the end it would seek to avoid.

I cannot help thinking that in this day of what we must do and what we *may not* do, this abundant care for the well-being of the individual in all directions, we are getting somewhat sickly in our views of health, and we are in *danger* of assuming the existence of a tripe-like heart, and overlooking the energetic attributes of living muscle? The heart does not become *dilated readily.* On the contrary, it is equal, and more than equal, to all the ordinary, and many of the extraordinary, emergencies of life. Ay, and I am glad *to insist* upon much more than that, for, as *you all* well know, *even under the stress of serious* incurable disease its energy will keep its failing powers going for much longer than our poor forecast gives it credit and that *sometimes it is* all the better for being so called upon. I cannot give a better illustration of this than the case of mitral stenosis.

When we consider that *nearly always* the contraction of the valve must take years to mature and even when it is apparently fully come it may last, as I can say, for 20 years, the subject even living a fairly active and useful life, one may well carry the lesson to other *forms of heart disease* and deal a little less extravagantly with the principle of rest. I often see, as I think, this treatment pushed too *far,* or perhaps *I ought* rather to say that judging no man I often ask myself, Is this good or bad treatment? I see people absolutely forbidden to walk up hill or exercised—no, aired only—in a bath chair, or *carried* up and down *stairs,* or pinned to bed, and I feel inclined, with the world, the flesh, and the Devil of my earlier years, to renounce them all. I daresay I am wrong, but it is seldom indeed that I order anyone to be carried upstairs. It should be reserved for well considered emergencies that seldom come, *and Oertel's suggestion of graduated exercise* up hill I believe to be a most valuable one, provided that it is taken very slowly and with the mouth open. In this frame of mind one will make mistakes. I sadly and sorrowfully admit it. Indeed, in the mood of the great Napoleon, I must say I have been mistaken so often I no longer blush for it and, no doubt, after having given a positive opinion in favour of a *sound heart a sudden death will now and again* come to torture you and as it were to make you hesitate in the course marked out. Such things *may* well quicken our perception and go to render our judgment more keen. But none the less I am *sure* of this, that we do *far* more good in our day by pronouncing people sound, if *out* of health, and by sending them forth with strengthened hope, than by keeping them in the *chains of uncertainty and nervous dread, than* which nothing can be more crushing to the utility of a life or more harmful to the chance of regaining health.

Years ago there was a discussion at one of the societies upon *aneurysm* of the aortic arch, and I, having made the remark that it was practically an incurable disease, as judged from the evidence of the post-mortem room and the *museums,* and so it is, Sir William Broadbent promptly and felicitously retorted that the post-mortem room was not the place to look for cures! I was quick to see then that what seemed an obvious truism did but dissemble the truth, but to-day and here I am *older* and I *now see that other face with fuller meaning,* which then perhaps I slighted. And so I have availed myself of the honour you have done me to discourse to-night in other terms upon the buoyancy of life and to preach that it is not well to seek too much for the dead amongst the living. To ask you to accept my opinions would be the last thing that I would do but I may ask you to *think them* over and welcome *anything that* may be *agreeable thereto* with your own experience.

THE REACTION OF PHENYLHYDRAZI WITH OTHER SUBSTANCES THAN DEXTROSE OCCURRING IN THE URINE.[1]

BY P. J. CAMMIDGE, M.B. LOND., D.P.H. CANTAB., &C.

THE application of phenylhydrazin as a *reagent for* th detection of sugar in the urine marked an epoch in the i vestigation of glycosuria and allied conditions; *for not* onl is it much more delicate than any test previously employe but *it* is unaffected by other substances such as creati creatinin, hippuric acid, homogentisic acid, and excess c uric acid or urates, as met with in human urine, that a liable to give rise to difficulties when most other metho of detecting sugar are relied upon. This reagent has als the advantage of allowing the various forms of carb hydrate *to be distinguished.* This is a *matter* of som importance, for although dextrose is undoubtedly the com monest sugar met with in the urine, there is considerabl evidence to show that other forms of carbohydrate an allied substances occur more frequently than has been supposed and that their presence is associated with various abnormalities of metabolism. As more detailed attention is paid to the investigation of the urine in cases of supposed diabetes and some diseases in which glycosuria is likely to occur, our knowledge of the true significance of these rarer forms will be increased and possibly at the same time our information as to the mechanism of normal carbohydrate metabolism may also be added to. A brief survey of the more important characters of the phenylhydrazin compounds which may be derived from the urine may be of some service. The test is now frequently employed clinically, but it is not often that the investigation is carried further than the preparation of the osazone crystals and it is probable that much valuable information is missed in consequence.

[1] A paper read before the Royal Medical and Chirurgical Society o June 6th, 1905.

The method of performing the phenylhydrazin test described by von Jaksch has been much modified by subsequent writers and, since the physical conditions under which it is carried out materially affect the result, it will be necessary to refer to the chief variations proposed. Von Jaksch originally recommended[2] that 50 cubic centimetres of the urine to be tested should be mixed with two grammes of sodium acetate and from one to two grammes of phenylhydrazin hydrochloride, and that the mixture be heated in a water bath for from 20 minutes to half an hour. If glucose is present the osazone then separates out on cooling as an amorphous or crystalline deposit of a yellow or reddish colour. If amorphous, the precipitate can be recovered in a crystalline form by dissolving it in hot alcohol, diluting the solution with water, boiling to expel the alcohol and then cooling. This method of performing the test takes time and requires the use of special apparatus which is not always available. To obviate these difficulties and render the reaction convenient for clinical use it has been suggested[3] that 0·5 gramme of phenylhydrazin hydrochloride and 1·5 grammes of sodium acetate should be dissolved by gentle heat in a few cubic centimetres of water in a test-tube and then 5 to 10 cubic centimetres of the urine added. The mixture is brought to the boiling point and maintained there for three minutes with strong and five minutes with weak solutions of sugar. The test-tube is then set aside to cool and the deposit examined for osazone crystals in five or ten minutes. Some authorities, following E. Fischer,[4] have preferred to use phenylhydrazin and not the hydrochloride but it has the disadvantage of not keeping well. A knife-point of sodium acetate is added to 10 cubic centimetres of the urine, then from one to two cubic centimetres of 10 per cent. acetic acid, and five drops of pure phenylhydrazin introduced. The mixture is heated in the water bath or over the free flame in the same way as when the hydrochloride is employed. A recent modification of this method suggested by Kowarski,[5] which gives very satisfactory results and is more delicate, consists in mixing five drops of pure phenylhydrazin in a test-tube with ten drops of acetic acid, gently shaking and then adding about one cubic centimetre of a saturated solution of sodium chloride. To the solid mass that forms are added from three to five cubic centimetres of the urine and the test-tube is heated in the free flame for two minutes after its contents begin to boil. On cooling the osazone crystals separate from urines containing over 0·2 per cent. of sugar in one minute and from weaker solutions in about five minutes.

In whichever way the test is carried out a difficulty occasionally arises from the formation of a crystalline phenylhydrazin compound of glycuronic acid which is liable to be mistaken for the osazone of a sugar It has been stated[6] that prolonged heating tends to obviate this source of error, the glycuronic acid compound being precipitated on cooling as a brown amorphous mass and not in the crystalline form. In the examination of 100 normal urines I sought to test the truth of this statement and found that when heated in the water bath for an hour four of them showed a crystalline deposit, while by boiling in the free flame for five minutes six specimens gave a positive result. Using the same methods but shortening the period of heating to 20 minutes and two minutes respectively exactly the same results were obtained, so that the mere time or method of applying the heat cannot be relied upon to differentiate glycuronic acid from the sugars. In addition to dextrose, the sugars lævulose, lactose, maltose, isomaltose, and the pentoses, arabinose and xylose, have been described as occurring in the urine and forming compounds with phenylhydrazin. Glycuronic acid, as I have already mentioned, also forms a compound with this substance and exceptionally combinations with acetone, aceto-acetic acid, oxalic acid, and in very concentrated urines with uric acid may also be encountered. As human urine is relatively poor in uric acid, the last named does not call for further remark. The acetone compound occurs as needles which melt to oily globules at 16° C., while the oxalic acid salt separates as insoluble, glancing, colourless plates which melt at from 172 to 173° C. The phenylhydrazin compounds of the remaining substances possess certain physical and chemical characters by which they can be more or less readily differentiated. The chief of these are: (1) the rate of osazone formation; (2) the microscopical characters of the crystals; (3) the solubilities of the osazones in various reagents; (4) the melting points of the purified products; and (5) the percentage content of nitrogen.

1. The rate of osazone formation is a point of considerable importance in determining the variety of sugar present in a particular solution, for, as Marquenne has shown,[7] this is a property which has very characteristic variations for the different carbohydrates. Under experimental conditions, with solutions of definite strength, exact time-limits for the appearance of the osazone can be laid down. Although this is not feasible with such a liquid as urine, where the proportion of sugar present is unknown, valuable information can be obtained by observing the conditions and rate of osazone formation. The compound formed by dextrose and lævulose separates from the hot solution after a comparatively brief interval, the former in most cases with characteristic suddenness. The osazones of maltose, lactose, and the pentoses only form after much more prolonged heating and although crystals of pentosazone may eventually separate from the hot solution, maltosazone and lactosazone never appear until the fluid cools, no matter how long it may be boiled. In my experience the rapid method of performing the phenylhydrazin test gives a reaction with all sugar when ten cubic centimetres of the urine are used and the heating is continued for at least five minutes. In the water bath, however, even an hour is not sufficient to obtain a satisfactory yield with maltose, lactose, and pentose, an hour and a half or even two hours being required to demonstrate their presence satisfactorily, especially when the solution is weak. Those who prefer to use the water-bath method, therefore, and limit its time of application to 15 or 30 minutes can only expect to demonstrate dextrose or the more readily precipitated sugars and possibly also any glycuronic acid compounds that may be present in the urine.

2. Microscopical examination of the crystalline deposit obtained after treatment with phenylhydrazin shows certain differences in the characters, size, and arrangement of the crystals which are suggestive. The large yellow needles arranged in sheaves and rosettes yielded by dextrose are well known. Lævulosazone resembles glucosazone, but there is less tendency to rosette formation and the crystals are usually somewhat longer and more slender. Lactosazone occurs as spherical masses of crystals resembling a shaggy yellow chrysanthemum. At the periphery the separate crystals can be distinguished and are seen to be slender, flexible, and hair-like, but in the centre they are felted together into a brown semi-opaque mass. In preparations made by the rapid method the individual crystals are usually not as distinct as those formed after prolonged heating in the water-bath, the appearance presented being that of a brown central boss surrounded by a light yellow halo showing "fine" radial striations. The crystals of maltosazone are short, stiff, and sword like, and are arranged in small rosettes when prepared by the water-bath method. Preparations made by heating in the free flame are less characteristic, consisting of narrow crystals grouped in small bushy sheaves. Isomaltose yields masses of aggregated flexible needles of a golden-yellow colour, mostly arranged in spheres. The pentose crystals are silky, tangled, curved needles, generally arranged in rosettes. The shape, size, and arrangement of the crystals are influenced to a certain extent by the

manner in which the test is carried out and by the rate of cooling, so that not only is some experience of typical preparations required in forming an opinion but the physical condition under which the sample under examination was prepared must also be taken into account. In some cases the crystalline form can or[illegible] after the specimen has been [illegible]

3. The osazones can be di[illegible] by their solubilities. Thus, [illegible] in water at 60° C., but de[illegible] One part of lactosazone diss[illegible] water, while maltosazone is [illegible] to 75). Isomaltose dissolves 1 part in 4 of water at 100° C. I have found that the rate of solution of the osazones in dilute sulphuric acid is of some value in distinguishing the phenylhydrazin compounds of dextrose and lævulose from those of other carbohydrates. On irrigating a preparation of the latter with a 33 per cent. solution of the acid the crystals turn brown and dissolve rapidly, while dextrosazone and lævulosazone only slowly assume a brown colouration and take several minutes before they disappear. All the osazones are soluble in hot 50 per cent. alcohol and advantage is taken of this fact to prepare them in a pure form.

[illegible] the crystals obtained from urine by [illegible]on is one of their most useful and [illegible] The product employed for the purpose must, however, be pure, or doubtful and misleading results will follow. Thus, the melting point of pure dextrosazone is from 204° to 205° C. but the impure crystals obtained directly from the urine generally melt somewhere between 173° and 194° C. Lævulosazone melts at the same temperature as dextrosazone. The melting point of the phenylhydrazin compound of lactose is about 200° C. and of maltose from 206° to 207° C. Isomaltose begins to form drops at from 140° to 145° C., melts at from 150° to 153° C., and blackens at 200° C. The osazone of the pentoses in a pure form melts at 160° C., but as obtained from the urine the melting point lies between 156° and 158° C. As the osazones undergo decomposition on prolonged heating it is necessary that the temperature should be rapidly raised at first and then gradually increased as the point of fusion is approached, or charring of the specimen may obscure the change of state.

5. The formula of the osazones formed by the monosaccharides dextrose and lævulose is $C_{18}H_{22}N_4O_4$, while that of the disaccharides lactose, maltose, and isomaltose is $C_{24}H_{32}N_4O_9$. Hence the former may be expected to yield 15·64 per cent. and the latter 10·76 per cent. of nitrogen. In practice slightly lower readings are found to be the rule, about 15·58 per cent. being obtained for dextrose and lævulose and 10·67 per cent. or thereabout for the disaccharides. The percentage of nitrogen contained in the pentosazones is 17·07, as the formula is $C_{17}H_{20}N_4O_3$. By determining the percentage of nitrogen in an osazone it is therefore possible to decide to which of these three classes of carbohydrate the sugar belongs. A satisfactory determination is, however, only possible when a sufficient amount of the pure product and the necessary apparatus are available for a combustion experiment, as Kjeldahl's process is useless for the purpose, the separation of the nitrogen not being complete.

Consideration of the properties of the compound that a sugar forms with phenylhydrazin therefore enables one to distinguish between all the recognised varieties occurring in the urine save only dextrose and lævulose. Here reliance must be placed on other tests, such as the polariscope, Seliwanoff's test, and the reaction with methyl-phenyl-hydrazin. It is evident, however, that unless special care is taken the rarer forms of carbohydrate may readily be overlooked, especially if only small quantities are present, and that in some instances the method usually employed for demonstrating glucose will not suffice to reveal all that a more extensive use of the test would teach. It is consequently not surprising that comparatively little is known as to the occurrence in the urine and real significance of other varieties of sugar than dextrose.

Recent research has shown that lævulose is often present in diabetes along with dextrose, and it has also been described as occurring alone in mental depression, melancholia, and sleeplessness. Lactose is present in the urine of a considerable percentage of women during the puerperal period and is most marked when the breasts are gorged. Sucking infants with gastro-intestinal catarrh are also said to pass lactose in their urine occasionally. Hitherto maltose has only been met with in a few cases of disease of the pancreas and, so far as is known at present, its occurrence is confined to this class of case. Unfortunately, maltosuria is by no means a constant [illegible] and cannot therefore be reli[illegible] In an examination of 245 sp[illegible] disease of the pancreas by [illegible] have only met with two in [illegible] cha[illegible] for [illegible] deposit of crystals, probably also maltosazone, was given. One of the former was a patient in whom an operation for stone in the common duct with chronic pancreatitis had been performed four years previously. Isomaltose is prepared artificially along with maltose, in the reversion of glucose by the action of malt diastase, pancreatic juice, saliva, or blood serum on starch. It has been found in small quantities in apparently normal urine and up to the present it has not been determined whether its presence is associated with any particular metabolic disturbance or if an excess occurs under pathological conditions. Two varieties of pentose are encountered in the urine, a dextro-rotary and an optically inactive form. The former is found in alimentary pentosuria following in healthy persons the ingestion of pears, plums, cherries, bilberries, and other food materials containing pentose, while the latter is the form met with in chronic pentosuria and under pathological conditions. Only a few cases of chronic pentosuria have been described but more careful r[illegible] of the urine would probably show tha[illegible] more commonly mistaken for ordinary [illegible]nerally supposed. In a few cases of [illegible] and frequently along with dextrose in severe diabetes, pentoses have been reported as present in the urine. This is interesting in view of the fact that extirpation of the pancreas in dogs is followed by excretion of a pentose in the urine. In none of the cases of inflammation or malignant disease of the pancreas that I have examined has any evidence of the presence of this substance been found.

Glycuronic acid, the only other important substance forming a compound with phenylhydrazin that is met with in fresh urine, is closely related to the sugars. It represents an early stage in the oxidation of glucose where one atom of oxygen has replaced two hydrogen atoms in the group $CH_2—OH$. It is not found free in the urine but always in combination with various bases and with fatty and aromatic alcohols, especially the latter. In perfect health the amount excreted is small, but when the conditions are such that there is an excessive formation of phenol, indol, and similar products of putrefaction the excretion is correspondingly increased. It is well known that the increased reducing power of the urine after chloroform anæsthesia and the administration of certain drugs such as camphor, chloral, salicylic acid, turpentine, thymol, &c., is due, not to sugar, but to conjugated glycuronic acid which these substances cause to pass into the urine. In cases of respiratory difficulty and in febrile diseases an increased output of glycuronic acid is said to take place. The urine of diabetics often contains glycuronic acid, and even in severe cases the tissues appear to be able to carry the oxidation to this point, for the administration of appropriate drugs will cause a large amount to be passed. Large doses of sugar in the apparently healthy may be reflected in the urine by an increased excretion of glycuronic acid. Alkaline salts of the acid form a compound with phenylhydrazin, which slowly separates on cooling as yellow needles usually of a somewhat darker colour, of smaller size, and more irregular shape than the osazones of the sugars. Some compounds of glycuronic acid undergo the decomposition that must occur before it combines with phenylhydrazin more easily than others, so that the readiness with which the reaction takes place varies. A urine containing a compound such as urocholic acid, which readily splits up, quickly responds to the test but the more resistant phenol and indol compounds require prolonged treatment before they react. When the reaction takes place in a solution containing free acid the phenylhydrazin compound is precipitated in the form of dark-brown granules and does not assume the crystalline form. Prolonged heating is said to bring about a similar result but in practice this cannot be depended on to distinguish the sugars from glycuronic acid. The crystals are readily soluble in hot alcohol but generally separate from this solution after dilution with water and boiling in an amorphous form. In

33 per cent. sulphuric acid they dissolve in about one to two minutes. The melting point of the crystalline variety is 114°–115° C., but the amorphous form requires heating to 150° C. before any change is observed. Since the formula of the phenylhydrazin compound of glycuronic acid is $C_{42}H_{44}$, $N_{10}O_{12}$, it is calculated to yield 16·4 per cent. of nitrogen on combustion. It is not at all an easy matter, however, to obtain a sufficiently pure specimen from the urine to allow of an accurate determination of either the melting point or the nitrogen content.

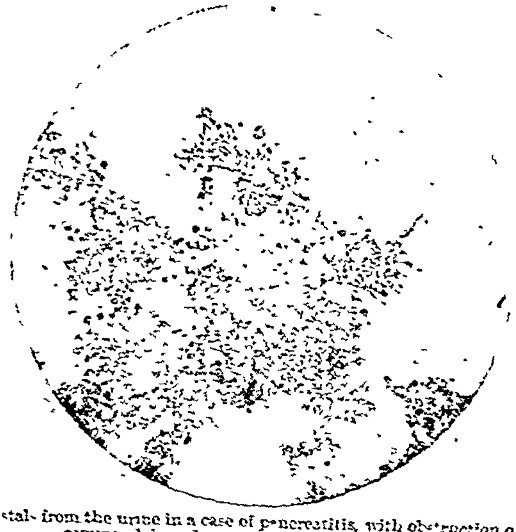
The freeing of glycuronic acid from its combinations is most readily effected by heating with dilute acids. Hence some urines that do not react with phenylhydrazin alone may do so after such treatment, and in others the yield may be materially increased. In an investigation with the phenylhydrazin test of a series of 100 urines from apparently healthy people, I found that in addition to the six already mentioned which gave a reaction with phenylhydrazin alone, 13 yielded a positive result due to glycuronic acid after treatment with hydrochloric acid. The series, on being divided into an earlier set of 43, derived from persons living in the country with an abundance of fresh air and exercise, and a later set of 57 obtained from city dwellers who lived under less favourable hygienic conditions, showed that none of the former gave a reaction until the urine had been boiled with acid, and then only three yielded a crystalline deposit, but that six of the latter gave a positive result before treatment and nine after.

Glycuronic acid is not the only substance capable of combining with phenylhydrazin that is set free in the urine by heating with dilute acids. Under certain pathological conditions an appreciable quantity of an osazone with a definite melting point differing from that of glycuronic acid may be obtained. It has been stated that when normal urines are boiled with one-tenth volume of strong hydrochloric acid for five to ten minutes and the excess of acid neutralised very characteristic crystals are "invariably" obtained with phenylhydrazin.[4] This is not by any means my experience, for in 94 normal urines that gave no reaction with phenylhydrazin I found that 19 gave a slight crystalline deposit and seven a more marked result after boiling with hydrochloric acid. Of these, 12, as I have already stated, were glycuronic acid compounds, so that in 14 out of 94 specimens from apparently healthy people there was a reaction due to some other substance. Only three of these were at all comparable in degree with what is met with pathologically and as all three were derived from persons living a sedentary life and occurred in my later series I think it is not unlikely that the reaction was an expression of a disturbance of function. In disease, especially where there are inflammatory reaction and marked tissue change or an affection of the kidneys, treatment of the urine with an acid previously to the application of the phenylhydrazin test produces a marked and in many instances a most striking effect if the operation is carefully performed. The details of the experiment, however, exert considerable influence on the result, and some experience is required to determine what conditions are best suited to obtain the most characteristic effect with the particular specimen of urine under examination. Insufficient or too prolonged heating after the addition of the acid may prevent the reaction or interfere with it, while unless care is taken in carrying out the neutralisation of the excess of acid the derivatives obtained may be destroyed or their presence obscured. Boiling in the water-bath for from 15 to 30 minutes is in my experience quite insufficient to secure a characteristic reaction with phenylhydrazin when this test is subsequently applied. To avoid the difficulties attending neutralisation with a caustic alkali I have generally employed a neutral salt that formed an insoluble compound with the acid—lead carbonate for hydrochloric acid and barium carbonate for sulphuric acid. Although lead chloride is soluble in hot water it is almost insoluble in cold, especially when there is a little free hydrochloric acid present. It is therefore essential in using this method, if difficulties from lead salts are to be avoided, that the solution should be well cooled before the carbonate is added and it is an advantage if a trace of hydrochloric acid is left unneutralised. Of course, the usual precautions in filtering off the insoluble lead compound are necessary. Sulphuric acid gives comparable results with hydrochloric and the more complete insolubility of barium sulphate is an advantage, but much more care is required to secure constant results. The fact that similar crystals are obtained from the same urine with both acids and with different methods of neutralisation indicates that those produced by the use of hydrochloric acid and lead carbonate are not lead compounds, as does also their not responding to any of the reactions for lead when isolated and purified.

My experience of this reaction has been chiefly gained in connection with work on diseases of the pancreas which I have carried out in conjunction with Mr. Mayo Robson. Up to Dec. 31st, 1904, I had the opportunity of examining 479 specimens of urine from 295 cases, most of the patients being under Mr. Robson's care, and on many of whom he performed an abdominal section.

In 130 cases the urine when treated with hydrochloric acid and neutralised with lead carbonate yielded with phenylhydrazin hydrochloride and sodium acetate a considerable flocculent brown deposit, which under the microscope was found to consist of yellow crystals smaller than glucosazone and generally arranged in rosettes. In some the crystals were slender and somewhat resembled small lactosazone or pentosazone crystals, while in others they were less delicate and approached the glucosazone or even maltosazone type in shape. Their time of solution in 33 per cent. sulphuric acid varied from half to one and a half or two minutes when the mean of several observations was taken. On being filtered off, washed, extracted with boiling 50 per cent. alcohol and re-crystallised they gave a melting point of from 168° to 170° C. (Fig. 1.)

FIG. 1.



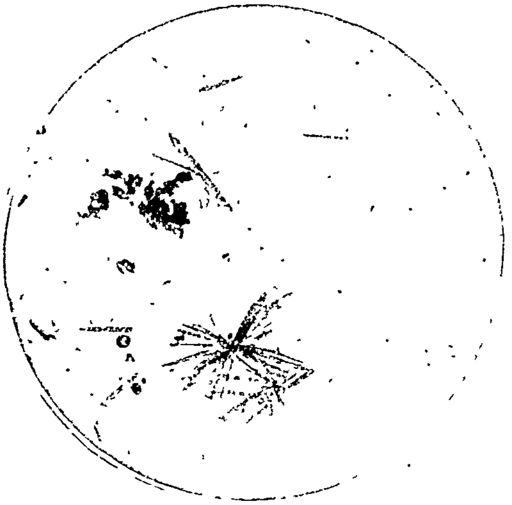
Crystals from the urine in a case of pancreatitis, with obstruction of the common bile and pancreatic duct by a gall stone.

The clinical symptoms in 116 of these cases pointed to disease of the pancreas, and in 79 it was possible to ascertain the condition of the parts at operation. In five the diagnosis was confirmed post mortem, shortly after the last examination of the urine had been made. Three cases in which fine rapidly dissolving crystals were isolated from the urine were found to be suffering from acute pancreatitis with fat necrosis. One succumbed shortly after the operation and was examined after death. In 37 gallstones were found impacted in the lower part of the common bile duct and the pancreas was stated to be unmistakably enlarged and hardened. In two cases a similar condition of the gland was found, associated in one with obstruction and considerable dilatation of the common bile duct and in the other with a malignant growth of the duodenal papilla which subsequently proved fatal. In two cases pancreatic calculi were found and in two others a cyst of the pancreas was dealt with. The pancreas was recognised as being enlarged and harder than usual in 29 cases, but no obstruction of the ducts could be found at the time of operation. In one case a malignant growth of the stomach was found adherent to, and growing into, the pancreas. In three cases, although there were gallstones in the gall-bladder or cystic duct, no abnormality of the pancreas to sight or touch could be detected. Three cases in which the urine during life gave a well-marked deposit of crystals were not operated on, but chronic pancreatitis was found after death. In another case in which the urine gave a similar reaction malignant disease of the pancreas was found post mortem. A clinical diagnosis of cancer of the pancreas was made in two patients whose urine gave many fine rapidly dissolving crystals. In one of these a large mass was found at operation occupying the head of the gland and probably compressing the duct. The clinical symptoms in 14 control cases did not suggest pancreatic disease but the urine gave a well-marked reaction. Of these patients, three were suffering from mumps, two from cancer with secondary deposits, two from disease of the kidney with albuminuria, two from fractured bones, one from peritonitis, one from chronic colitis, and one from pneumonia. A small deposit of crystals, considerably less than in the previous group, was obtained in 35 cases. In three of these the pancreas was probably diseased. One showed a small stone in the common duct and some enlargement of the gland. A history of gall-stone colic was present in the other two, and when examined at operation the pancreas was found to be enlarged and harder than normal. In the remaining 32 a lesion unconnected with the pancreas was found. A deposit consisting of broad, flat, sword-like crystals soluble in 33 per cent. sulphuric acid in from four to five minutes was obtained in 21 cases. Clinically these were all diagnosed as malignant disease of the pancreas but only two were operated on. One died a few days after the operation and the other lived for several weeks but finally died from the disease. 13 are known to have steadily got worse and died at later periods with secondary symptoms from malignant growth. In two a post-mortem examination was obtained and in both the diagnosis was confirmed. The crystals were difficult to secure in several instances and without the exercise of considerable care and patience it is quite possible that no result would have been obtained. In these cases of pancreatic cancer and in many others of suspected pancreatic disease much assistance in diagnosis was derived from a microscopical and chemical examination of the fæces. A few crystals were seen microscopically in the urine from 11 cases, but none of them showed any evidence, either clinically or at operation, of disease of the pancreas. (Fig. 2.)

---

[4] THE LANCET, July 23rd, 1904, p. 211.

FIG. 2.



Crystals from the urine in a case of malignant disease of the pancreas.

No reaction whatever was obtained in 93 cases. Two of these died and were examined a short time subsequently to the examination of the urine. The pancreas in both was found to be normal macroscopically and microscopically. 32 were operated on. In nine gall-stones were found in the gall-bladder or cystic duct but the pancreas was said to be normal. In three a calculus was found above the pancreatic portion of the common bile-duct and six showed a biliary concretion floating in the common duct but no affection of the pancreas. No obstruction of the common duct or disease of the pancreas could be found to explain the jaundice present in three cases. In two patients there was said to be pancreatitis when the gland was examined at operation. The remaining 59 cases were not operated on. In eight there was at the time the urine was examined a suspicion of pancreatic disease which the subsequent course of the case dispelled. 51 were control cases examined for the purpose of comparison; two had cancer of the liver, five gastric ulcer, and two ulcer of the duodenum, while the remainder suffered from diseases unconnected with the pancreas.

From the urine of three cases of pancreatitis and two cases of diabetes I succeeded in isolating a substance which gave the reactions of a proteid but none with phenylhydrazin. Solutions of this on hydrolysis with hydrochloric acid yielded a crystalline phenylhydrazin compound resembling that obtained from the urine directly. In consequence of this observation I was led to try the effect of treatment of the urine with mercuric chloride before hydrolysis. In 24 out of 126 cases in which the urine gave a reaction before treatment it was found that the addition of half its volume of a saturated solution of corrosive sublimate entirely prevented the reaction. Three of the patients were suffering from diabetes, and in one, where the pancreas was examined after death, it was found that almost the whole of the glandular substance had been replaced by fibrous tissue. In another the glycosuria had supervened eight and a half years after an operation for pancreatitis. Active pancreatitis associated with obstruction of the common duct was found in 17 cases. In four the pancreas was enlarged and hard but there was no obstruction. The reaction, although not completely prevented, was appreciably diminished in 30 cases. 24 of these were found at operation to have an enlarged and hardened pancreas, and in 11 there was a gall-stone in the common duct. Two were diagnosed as cancer of the pancreas and ended fatally. One case with an affection of the kidney, one with mumps, and one with advanced carcinoma of the breast, showed some diminution in the amount of the deposit. No appreciable difference was observed in the urine of 69 cases. Of these ten were found to be suffering from pancreatitis, which in four was known to be of some standing. In 14 a diagnosis of malignant disease of the pancreas was made. The remainder were cases in which the results of operation or the clinical condition and after-history of the case negatived pancreatic mischief.

With nitric acid (0·25 cubic centimetre to ten cubic centimetres of urine) similar results to those described with hydrochloric acid and sulphuric acid have been obtained, but the reaction has been found to be more difficult to control. Crystals of a kind can be prepared in most circumstances from suitable specimens of urine, but with care those cases in which there were obstruction of the common duct and marked swelling of the pancreas have been found to yield small masses of fine lemon-yellow needles quite distinct from the brownish sheaves with which they were generally mixed. As the excess of nitric acid left after heating cannot be removed as an insoluble salt, and as even a slight excess of alkali has been found to interfere with the subsequent course of the reaction, the fluid is diluted with ten cubic centimetres of urine, made up to 15 cubic centimetres with water and a slightly larger amount of sodium acetate added with the phenylhydrazin hydrochloride than usual. I may here mention that by heating a solution of glycerine with nitric, *not* hydrochloric, acid and neutralising with urea I have repeatedly obtained on treatment with phenylhydrazin an osazone with a melting point of 131° C., and that it was on this fact that the original investigations on the urine in diseases of the pancreas were founded.

It is evident that in phenylhydrazin we possess a most useful reagent for inquiring into variations in the urine accompanying certain changes in metabolism. In the hands of those who have had some experience of its application and the interpretation of the results that may be obtained by its use the test is capable of more than the detection of traces of dextrose in slight or doubtful cases of diabetes, important as this may be. Although advocating a more extended use of this test in the examination of urine I do not wish it to be thought that I am underestimating the value of other reactions or methods of investigations. Like most laboratory methods in the present state of our knowledge it has its limitations and needs to be interpreted in the light of all the available evidence, not only from a complete chemical and microscopical examination of the urine but also from the clinical aspects of the case and in certain circumstances from the investigation of the fæces, or blood, or other "products."

Beaumont-street, W.

URIC ACID.

A RATIONAL TREATMENT FOR ITS ELIMINATION, IN THE LIGHT OF RECENT RESEARCH.

By ROBERT FENNER, L.R.C.P. EDIN., M.R.C.S. ENG.

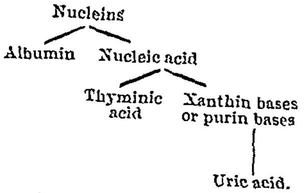
THE causes and treatment of those diseases depending upon an excess of uric acid in the blood and its deposition in the tissues of the body have been shrouded for years in mystery and the recorded theories founded on clinical research are fraught with fallacies. As a subject it is of the utmost importance to the practising physician. In few other troubles are his remedies and treatment so impotent. Many have been the theories but the advance in treatment has been practically *nil*. The main object of all treatment hitherto has been to prevent the accumulation of the salts of uric acid in the system and to favour their excretion, but no attempt has been made to deal with uric acid *per se* or to prevent the formation of the urates. A great variety of drugs have been exploited and are in daily use to rid the system of their presence after their formation. It is much as if the stable door be shut after the horse has disappeared. With all diffidence I hope, on the basis of recent researches by Minkowski, Kossel, and Schmoll, to prove that there is a substance which, by holding uric acid firmly in solution, prevents its deposition in the tissues in the form of salts; that this substance answers the chemical and physiological tests required; and that its exhibition is clinically successful in those cases which depend upon an excess of uric acid in the blood.

Gout has been generally considered to be an acute arthritis associated with a deposit of crystalline sodium biurate in the joints affected and with a circulation of an excess of urates in the blood. According to the usually accepted theories the excess of uric acid in the blood is due either to (*a*) increased production or (*b*) decreased elimination by the kidneys. Garrod adopted the second view. Roberts[1] gave it as his opinion that the sodium salt present is the quadriurate and if this is in excess or not rapidly eliminated it forms sodium biurate by coming into contact with sodium carbonate, but Fischer conclusively proves that the quadriurates are a mixture of the urates and uric acid in its free state. Murchison[2] thought that there was excessive formation of uric acid through deficient oxidation of the ingesta owing to functional inactivity of the liver and therefore he considered uric acid a half-way product in the oxidation of albuminous foods. Latham suggested the theory that the increase of uric acid was due to the imperfect metabolism of glycocine in the liver.

Haig[3] has given us a most interesting and entertaining volume upon uric acid, in which almost all "the ills that flesh is heir to" are stated to be due to some form of uric-acid poisoning and these may be divided into two groups: (*a*) gout and (*b*) collæmia. He advances the theory that "gout is relieved by solvents, collæmia by retentives. Both are prevented, relieved, or wiped off the record by a uric-acid-free diet. Gout is accompanied by a quick circulation, raised temperature, and a few granules in the blood. Collæmia is accompanied by a slow circulation, subnormal temperature, and many granules in the blood—both are the results of excess of uric acid in the body and that excess is produced by swallowing it in the food." In collæmia he thinks that uric acid is present in the blood as a colloid or gluey material and mechanically blocks the capillaries, causing: "1. High blood pressure in the arteries. 2. Increase in the heart's work. 3. Obstruction of the capillaries. 4. Defective combustion." His dietetic treatment is important, as he certainly aims at the reduction in quantity of the uric acid itself, for he only allows his patients those foods which are calculated to sustain life in birds and rodents. One's experience in practice is that patients will not endure a treatment which deprives them of most of those foods which make ordinary life worth the living, and for whose digestion our organisation has been fully adapted by a beneficent Creator. His theory might hold good in the case of a gouty person in whom it is all-important to restrict the formation of free uric acid but in a healthy person the foods which he forbids are absolutely necessary for sustained and vigorous life, where the ingestion of nucleins is followed by an adequate metabolism. As will presently be proved the uric acid not only becomes perfectly soluble in the blood stream but is maintained in that condition and prevented from being deposited in the tissues by a substance formed at the same time and with which it unites in indissoluble bonds. The important part of Haig's treatment is his clear insistence that it is the irritating presence of uric acid itself in a fibrous tissue, "either in solution or suspension," that is the cause of trouble in his (*a*) group, and the excess of uric acid in the blood the cause of trouble in his (*b*) group. In the absence of all scientific proof and the results of research his theory must remain a pious opinion.

Before considering the rôle that uric acid plays in the production of gout it is important to consider its relationship to nutrition. In striking contrast to urea uric acid requires for its solution 16,000 parts of cold water; it is therefore clearly impossible for uric acid to be present in the blood as an acid unless it is in combination with a substance which makes it easily soluble. It is dibasic and has the formula $C_5H_4N_4O_3$. It forms two classes of salts of which the solubility is almost equally deficient; these are the urates and the biurates: (1) Normal = 2 atoms of H replaced by 2 of Na = $C_5H_2Na_2N_4O_3$ = urates. (2) Acid = 1 atom of H replaced by 1 of Na = $C_5H_3NaN_4O_3$ = biurates. This latter is the chief constituent of the pinkish so-called "lateritious" deposit. It has been proved that uric acid is not made in the kidneys; when these have been removed it continues to be formed and accumulated in the organs, notably in the liver and spleen. In birds, when the liver has been removed, uric acid is scarcely found at all, its place being taken by ammonia and sarcolactic acid, therefore we may assume that uric acid is formed synthetically in this system; of this important fact I shall write later. The conditions which lead to an increased elimination of uric acid in the urine are: 1. An increase of meat diet and a diminution of oxidation which may be brought about by a sedentary life. 2. An increase of white corpuscles in the blood as in leucocythæmia. The leucocytes contain large quantities of nuclein and nuclein yields the xanthin bases to which uric acid is very closely related.

Uric acid had for long been considered a product of the imperfect oxidation of albumin before the formation of urea. Differing from Garrod, Bouchard[4] suggested that its increase in the serum and in the urine was due to defective oxidation and that this was the pathogeny of gout. But careful chemical research, the discoveries of Fischer[5] as to the connexion of uric acid with the constituents of the xanthin bases, and the results of physiological researches by Kossel[6] all point to the true origin of uric acid which is totally at variance with the hitherto accepted theories. There are three great classes of proteids: 1. Albumin, the protoplasm of the living cell containing no phosphorus. 2. The paranucleins, the properties of which are similar to the albuminoid bodies except that they contain a small percentage of phosphorus. They are represented by the yelk of egg and the casein of milk. 3. The nucleins, which constitute the chromatin fibres of the nucleus containing a fair proportion of phosphorus. By the splitting up of the nucleins, as shown by Schmoll, we obtain: (*a*) albumin (as in protoplasm); and (*b*) the nucleic acid group: thus



The nucleins when split up by digestion yield simple albumin and nucleic acid, nucleic acid again yielding thyminic acid and the xanthin bases. Fischer[7] after

TABLE I.—CASES OF ACUTE GOUT.

Case.	Sex.	Age.	Previous history.	Present attack.	Dose.	Remarks.
1	M.	46	Had had repeated attacks of acute gout in foot and knee extending over the last three years.	Right metacarpo-phalangeal joints swollen, inflamed, and painful.	4 grains three times a day.	Cured in five days; attacks usually lasted weeks.
2	M.	42	Had had two or three previous attacks.	[illegible]	5 grains three times a day.	Perfectly well in four da vious attacks had last seven to ten days.
3	M.	45	Subject to acute gouty synovitis of right knee and pharyngitis.	Painful inflammatory swelling of knee.	4 grains every four hours.	The knee was well in five the pharyngitis yielded to this treatment.
4	M.	55	Had suffered with various manifestations of acute gout at intervals during the past six years. Had traces of albumin and a quantity of sugar in urine.	Acute dyspepsia with vomiting and gouty pharyngitis.	"	The acute symptoms appeared in five days; ninth day sugar reduc 3·13 grains per ounce grains per ounce. Has more attacks since taking of thyminic acid twice The sugar has practic appeared.
5	M.	68	Had been subject to gout for years, having had several attacks of acute arthritis; usual duration of attack from three to four weeks.	Acute arthritis of left knee.	4 grains every four hours begun on second day of attack.	Cured; inflammation diss in four days.
6	F.	65	Had had several attacks of gout during the past four years; usual duration several weeks.	Severe attack in left foot and ankle.	4 grains three times a day begun on third day of attack.	[illegible] had another attack wh cured as quickly.
7	M.	54	Had repeated attacks of articular gout lasting from 10 to 15 days.	Acute arthritis of left ankle.	4 grains three times a day.	Cured in four days

TABLE II.—CASES OF CHRONIC GOUT.

Case.	Sex.	Age.	History of illness.	Dose.	Remarks
1	F.	70	Had suffered for many years with gouty arthritis of the finger-joints and knees and latterly with obstinate eczema and bullæ of the hands.	4 grains three times a day after food	Great improvement after one month's treatment walk with comfort a [illegible] weeks the eczema a [illegible] on small doses has k
2	M.	37	Tender swelling in the middle metacarpophalangeal joint of the right hand.	4 grains three times a day.	[illegible] of thyminic acid the [illegible] swelling diminished,
3	F.	45	Swelling and tenderness of the feet.	"	In one week the condition was so much impro she could walk with comfort.
4	F.	50	Stiffness in joints and back; gouty enlargement of finger-joints; excess of uric acid and urates in urine.	7 grains three times a day.	After three weeks there was an increased output acid, the urates disappeared, and the stiffness w improved,
5	F.	69	[illegible] painful.	"	Well-marked improvement in a fortnight, han free from pain, knees have recovered shape and and all the joints are more flexible.
6	F.	65	Sub-acute arthritis, especially of knees. Acid dyspepsia and constipation.	4 grains three times a day.	Arthritis improved steadily, also the dyspeps
7	M.	63	Gouty pains in left hand, tophi on little finger-joints of both hands, eczema on arms and thighs.	7 grains three times a day.	Improvement very marked, eczema disappear
8	M.	35	Had suffered with extensive psoriasis of chest, back, arms, and legs, which had resisted all treatment for several years.	8 grains three times a day.	In a fortnight there was marked improvement; [illegible] had disappeared but patie [illegible] d; has again almost dis [illegible] it by thyminic acid, t supplemented by 14 days' Zittmann's treatment.
9	M.	57	Gouty glycosuria occurring in the course of an attack of laryngitis; amount of sugar = 8 grains to the ounce.	4 grains three times a day.	The sugar gradually diminished in quantity and disappeared in 14 days; has not recurred. The takes occasional doses of thyminic acid.
10	M.	46	Gouty glycosuria. Sugar = 29·14 grains per ounce. A great gourmand and an alcoholic.	8 grains three times a day.	In one month the amount of sugar fell to 8·75 gr ounce, in two months to 3·64 grains per ounce residing abroad, in good health.
11	F.	43	Suffered from obesity, periodical headaches, sleeplessness, and dyspepsia.	4 grains three times a day.	After three months' treatment the patient had l pounds in weight, the headaches, dyspepsia, an [illegible]
12	M.	48	Gouty laryngitis and eczema of hands. Tophi present on ears.	"	Cured after two weeks' treatment, but patient careless liver symptoms again returned but are disappearing under treatment.
13	M.	46	Had suffered with repeated attacks of "gravel" for the past five years.	"	After six weeks' treatment, during which time he from pain, he had an attack of renal colic which e the passing of a small uric acid calculus; since has been perfectly well.

[illegible] the xanthin bases, conceived them to [illegible] and called them "the purin bodies." The most simple representative of the purin bodies is hypoxanthin, which contains in its molecule one atom of oxygen, and by adding first one atom of oxygen and then two to this substance we obtain successively xanthin and then uric acid, or if the amido group be introduced into the purin nucleus adenin and guanin result, the latter containing one atom of oxygen, the former none. Therefore starting from purin bases we can, by simple chemical changes, obtain uric acid. These purin bodies are found in the organism wherever there are nucleins. The xanthin bases found in the human body are principally adenin and guanin; the bases can thus be combined with thyminic acid to form nucleic acid, as is shown by the following rough scheme: nucleic acid = adenin + guanin + thyminic acid.

Remembering that nucleic acid, by splitting up, yields, ultimately, uric acid and thyminic acid, and basing their theory on the presence of thyminic acid with the intra-organic formation of uric acid, Minkowski[8] and Kossel[9] advanced the hypothesis that thyminic acid is the substance which combined with uric acid renders the latter soluble and that this combination cannot readily be broken up and together they form a product no longer precipitable either by acids or heavy metals, in fact, uric acid cannot be recovered after it has once combined with thyminic acid without prolonged boiling. *Granting that this supposition is correct* we can at once form an exact idea of the action of uric acid in the body. As soon as *formed* uric acid combines *with thyminic acid*. In this combination it *circulates in the blood* and this prevents its detection in *normal serum*. It is excreted by the kidneys, partly in its combined state and partly after the breaking up of this combination. The presence of thyminic acid in health explains why uric acid in the urine is not entirely precipitated by acids. Weintraud[10] has demonstrated the connexion between nucleic and uric acid *by showing that after ingestion of thymus gland extract*, which is essentially rich in nucleins, the *excretion of uric* acid rose from 0·5 gramme to 1·8 grammes and 2 grammes in 24 hours: Hess and Schmoll[11] have shown that the nucleins were the sole origin of uric acid. It was shown that in a healthy person, on a regulated diet, the only way *in which the excretion* of uric acid could be altered from its normal percentage was by *giving* foods containing purin bases! The administration of albuminoids brought about no alteration in the quantity excreted. Garrod[12] established the presence of *uric acid* in the gouty blood serum and the relation between a gouty attack and deposit of uric acid in the joints. He explained the presence of uric acid in the serum on the hypothesis that it was merely retained there and the deposits were explained in a similar way. There is, however, nothing to indicate any connexion between the excretion of *uric acid* and its *presence* in gouty serum. It has been proved that in the healthy physiological state uric acid cannot be found *in the blood serum. It is not formed* in the kidneys, and before its excretion it has to be carried away in the blood stream. Thus all analyses are tainted with error, since we cannot detect uric acid in combination with thyminic acid, and *in no other form* does it exist in the blood in a physiological state. The presence of uric acid in gouty fluids and *tissues may thus be explained* by the absence of a proper proportion of *thyminic* acid combined with it and keeping it in solution. In the normal state uric acid is produced by the oxidation of the *purin* bases; in the gouty state the combination with thyminic acid does not take place. If thyminic acid be given to gouty people uric acid combines with it, as has been experimentally proved by Schmoll.[13] It is possible, therefore, that in gout uric acid *has* an origin other than from the nucleins in which thyminic acid is not at the same time produced.

Minkowsky has clearly demonstrated the synthetic production of *uric* acid in birds and Wiener[14] has established it in animals. The former has proved that all the acids with a chain of three atoms of carbon and two groups of acids can be transformed into uric acid by birds in the presence [illegible] ion of uric acid is of a [illegible] always leads to the formation of nucleins, but in the gouty diathesis this synthesis stops at uric acid and it is this amount of acid the presence of which we can prove. In nephritis the presence of uric acid might be due to the fact that the combination of thyminic acid and uric acid is destroyed in the kidneys. Obviously this might also explain its presence in gouty serum but the results of Schmoll's experiments conclusively prove that the excretion of uric acid in gout is enormously increased by the ingestion of thyminic acid, thus refuting the above hypothesis. We may thus express the pathogeny of gout. Uric acid in a gouty organism is formed synthetically, whilst in the normal state it is formed by oxidation; in the latter case thyminic acid, which is always present, combines with uric acid, and it is in this combination that uric acid circulates in the blood. The absence of thyminic acid in gout explains how uric acid is precipitated and found in the serum. Schmoll has made a series of experiments proving the pronounced influence of thyminic acid on the excretion of uric acid in gout; it was increased in every case from 25 to 50 per cent. Another series of experiments on a normally healthy man showed that the ingestion of thyminic acid produced no result.

What, then, are the properties of this substance which holds uric acid in such a grip that, in health, no splitting up can occur and consequently no urates can be deposited *in the tissues or joints*? A combination so firm that uric acid cannot even be detected in the blood! I have preferred to call this substance "thyminic acid" rather than the "*thymic acid*" of Schmoll (which might lead to confusion with the products of the herb thyme) or the somewhat clumsily called "nucleotin-phosphoric acid" of Minkowsky and Walker Hall.

Walker Hall, in his valuable handbook on "Purin Bodies," p. 189, says: "An interesting outlook in relation *to this question is the action of some bodies which hinder or prevent the precipitation of uric acid and xanthin bodies from their solutions. Minkowsky* some time since remarked upon this property of nucleotin phosphoric acid and has administered this *substance* to patients with the view of *maintaining* the circulating purins in solution and preventing uratic infiltration. At present, however, nucleotin phosphoric acid is not easily obtainable and very few results are *recorded*." *In an interesting discussion on the Chemical* Pathology of Gout[15] A. E. Garrod says: "We do not know *in what combination uric acid exists in the blood of the gouty: and I would venture to suggest that this question offers a promising line for investigation—an investigation which is by no means easy at the present day when* venesection is no longer in fashion."

Thyminic acid is an amorphous powder, brownish-yellow in colour, soluble in cold water, slightly deliquescent, faintly acid in reaction, and almost tasteless; Minkowski gives its formula as $C_{33}H_{47}N_4O_{14} \cdot 2P_2O_5$; Kossel as $C_{16}H_{25}N_3P_2O_{12}$. It has the very interesting property of holding in solution practically its own weight of uric acid at a temperature of 20° C., while this property of retention is increased by 50 per cent. at the blood temperature of 37° C. This can easily be confirmed. A slightly alkaline solution of sodium or potassium urate is prepared in a test-tube, care being taken to use only a very small quantity, one-eighth of a grain or even less. In another test-tube a solution is made of a somewhat larger quantity of thyminic acid. Half of the contents of each of these test-tubes is then poured into a third and shaken up together; if the mixture be strongly acidified it will be noticed that the uric acid is *held firmly* in solution and is not precipitated. If, *on the other hand*, the test-tube containing the remaining half of the uric acid solution be filled up with water and rendered acid the uric acid will either come down as an amorphous precipitate, or if the solution be weak crystals of uric acid will be slowly formed. According to Kossel, Goto,[16] and others the "retention property" of thyminic acid is increased when a small quantity of nucleic acid is present. Thyminic acid may be given internally as a *powder*, in an elixir, or in the form of compressed tablets. *Its administration* has not, in my experience, been attended by *any toxic* or untoward symptoms. It is best given with or immediately after meals, in doses of from four to seven grains; in solution it has practically no incompatibles.

During the past 16 months I have had under my care a great number of suitable cases for whom I have prescribed the thyminic acid prepared by Messrs. Allen and Hanburys, Limited. I usually order this to be taken in doses of from four to eight grains in the tablet form after meals; during its exhibition I have prescribed no other drug and the results have been most gratifying. In acute cases it quickly cuts short the inflammatory condition and leads to rapid convalescence; in chronic cases prolonged administration of the drug has led to marked improvement in nearly every case. I have been particularly pleased with the results of treatment in cases of gouty glycosuria, gravel, gouty eczema, and obesity. The accompanying cases have been selected at random from my own practice and from those of Dr. A. Butler Harris, Dr. W. M. Abbot Anderson, and Dr. Eugene F. Cronin, to whom I am indebted for having kindly sent me a record of many cases treated by them. I must also acknowledge my indebtedness to Mr. Alfred C. Chapman, F.I.C., F.C.S., for much valuable help received in difficult chemical research and experiments.

NOTE ON THE RECENT OUTBREAK OF TYPHOID FEVER AT LINCOLN.

BY E. CECIL CLEMENTS, M.R.C.S. ENG., L.R.C.P. LOND.

THE Lincoln epidemic of typhoid fever is fresh in the memory of most of us and although perhaps sufficient time has not yet elapsed to enable us to form a critical judgment exactly as to what we may learn from it, nevertheless I venture to think that the following observations, based upon 192 cases, even if somewhat crude, will not be valueless.

The Drill Hall temporary hospital was opened on Feb. 9th and I had under my care in the hospital 192 cases. 70 patients were admitted in four days; in the majority of them no clinical history could be obtained and it was thus impossible to estimate with any degree of accuracy the stage of the disease upon admission. Of the 192 patients 28, or 14·5 per cent., died. Of these 28 deaths eight were due to perforation. One case was treated surgically, the result being fatal. Eight deaths were due to hæmorrhage from the bowel, three deaths were caused by meningitis, and four by pulmonary complications. In only four cases did death follow an uncomplicated course. In 28 cases, or 14·5 per cent., relapses occurred; three of these had a second relapse and one had a third relapse. All the patients who experienced relapses are now convalescent. 44 patients presented marked cerebral symptoms; five of these, of whom three died, had undoubted meningitis. One patient was the subject of chronic pulmonary tuberculosis, having a cavity in the right apex. She recovered and the tuberculous condition seems at the present time improving. Four patients were pregnant and none of these aborted or miscarried. 29 cases ran a pyæmic course, characterised by numerous abscesses requiring surgical treatment. In ten cases the normal subsidence of fever was interrupted by a rigor which in most cases was severe. The patient would complain of feeling cold, violent shivering, and the temperature would run up to 103° or 104° F., settling down to subnormal within 24 hours and remaining there. The explanation of this would be interesting. Might it be due to separation of sloughs, as in one case where sloughs were recognised in the stool the temperature immediately came down to normal, but no definite rigor was noticeable?

Of the sequelæ observed in this epidemic up to the present time the most important was thrombosis, which occurred in nine cases. Ten patients suffered from suppuration of the ear; in four of these the previous history showed this affection to be definitely post-typhoidal. In one patient loss of memory and melancholia occurred three weeks after discharge from the hospital. Both these symptoms disappeared after three weeks' rest and sea-air. Three cases showed signs of slight peripheral neuritis. One patient is still under treatment for choroiditis.

The routine treatment that we adopted can best be considered under the following heads:—

Drugs.—An extensive trial was given to intestinal remedies such as salol, urotropine, &c. In no instance can I record any definite advantage from their use and in the later cases they were discarded. In cases of threatened cardiac or respiratory failure small doses of tincture of digitalis (from five to ten minims), but if sickness were present liquor strychninæ (from three to five minims), were given. It was found, however, that strychnine was apt to cause hunger. The sedative which after many trials was universally adopted was opium, which was generally supplemented by the application of icebags to the head. The form of opium used was the liquid extract. Morphine and chloral were nothing like so constant in their sedative effects and were after a preliminary trial discarded. Phenacetin was used in ten-grain doses as a sedative and antipyretic, either alone or combined with sal volatile or citrate of caffeine. The antipyretic action of this drug was very marked and was always accompanied by profuse diaphoresis. When combined in the above manner no marked depression followed its use and I have often seen it cause a fall of temperature (four or five degrees) about four hours after and be followed by a refreshing sleep. Tepid sponging was adopted as a routine practice when the temperature reached 104°. Its result was very varied and sometimes only lasted for an hour. Speaking generally, it was least useful in children and young adults. The highest temperature observed in a patient who recovered was 105·8°. Stimulants were used sparingly, only brandy in small doses being administered when necessary.

Purgatives.—Perhaps the mention of this class of drug may cause some surprise, but a very marked feature of the Lincoln epidemic was the absence of diarrhœa. Of 192 patients, only 24 suffered from anything approaching diarrhœa. Of these 24, in six patients the diarrhœa was profuse, in 11 it was medium, and in seven it was slight. More that 70 per cent of the patients suffered from parsistent constipation and this was treated by soap-and-water or olive-oil enemata or by the administration of castor oil by the mouth. These measures invariably relieved the symptom in question and in no case did any untoward result follow their use.

Hæmostatics.—As 33 cases of bad hæmorrhage occurred with eight deaths one had ample material upon which to estimate the relative value of hæmostatics. Various new drugs, such as adrenalin, were used. These preparations did not give very satisfactory results and were eventually discarded in favour of pilula plumbi cum opio (B.P.).

Dietetics.—The dietetic treatment of typhoid fever is a subject upon which so much has been written that if I had not what I believe to be a fresh experience to record my remarks would have been very brief. It frequently happened that during what was estimated as being the third week of typhoid pyrexia the patient's strength was at the lowest possible ebb. In these cases it was felt that in addition to the use of stimulants, which on account of their tendency to increase the cerebral symptoms had to be used with great caution, some strengthening of the milk diet must be resorted to. In this connexion an extensive trial was first of all made with a number of so-called bland meat proteid, albumose, and peptone preparations. It was found that these were ill borne by the patient and, in the main, were followed by an increase in abdominal pain and distension, in most cases culminating in diarrhœa, sickness, and even an increase in pyrexia. Subsequently a trial was made of various milk foods, especially of those consisting of either simple milk proteid or foods the essential basis of which was milk and farinaceous material partially or entirely converted by the action of a ferment into a soluble form. My experience with these latter foods was that they were of distinct value after the temperature had been normal for from six to eight days. I made several attempts to use them at an earlier date during the continuance of slight pyrexia but invariably found that they caused abdominal distension and discomfort, and in two cases definite increase of pyrexia. I also determined to give sanatogen a trial. It was given in two teaspoonful doses three or four times a day and was added to the milk according to the directions supplied. The cases in which it was at first used may be divided into three classes; first, those whose temperature had been normal for a few days before the treatment was started; secondly, those patients who still had a continued evening pyrexia ranging from 100° to 101°; and thirdly, those in the height of pyrexia. Owing to the extreme difficulty of obtaining accurate clinical histories it is impossible to say at exactly what period of the disease this second class was but apparently it ought to have been convalescence but for the severe asthenia. In the first class f patients, about 15 in number, the condition improved apidly, but no deduction of value can be drawn from the fact, as the patients were convalescing. In the second class f patients, some 20 in number, the temperature range became less and the asthenia improved. So far as concerns the third class there was at any rate no increase in pyrexia or gastro-intestinal disturbance.

CHARCOT'S DISEASE OF THE ANKLE IN A CASE OF GENERAL PARALYSIS OF THE INSANE.

By W. BILLINGTON, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS AT THE QUEEN'S HOSPITAL, BIRMINGHAM;
AND
A. STANLEY BARNES, M.D. LOND., M.R.C.P. LOND.,
PATHOLOGIST TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

THE following case of Charcot's disease of the ankle occurring in a man with symptoms of early general paralysis of the insane met with in the practice of one of us seems worthy of being recorded.

The patient, aged 37 years, complained of swelling of the left ankle together with weakness of the foot and some pain on walking. The history of the case showed that the patient had led a dissipated life and until the last six months, during which he had been a teetotaler, he had for years consumed upwards of a pint of spirits a day. At the age of 27 years he had had an attack of gonorrhœa and when he was 32 years of age he had contracted syphilis. A year later there was a sudden onset of cerebral thrombosis which left him partly paralysed on the right side. The paralysis lasted for several months and right-sided movements were still performed awkwardly. For the last three years he had had shooting pains in the shoulders, the shins, and the feet; the pain used to come on suddenly and to last for about half a minute. Six months ago his memory began to fail and for two or three months he had complained of precipitate micturition and occasional incontinence of urine. Three months before coming under observation his left ankle suddenly and without trauma became swollen. At first there was some pain but this soon subsided. The ankle remained swollen and was weak when weight was put upon it.

On examination the patient was found to be a well-nourished, powerfully built man. His mental condition was one of childishness; he was cheerful, readily interested, and on account of his simplicity became the butt of his friends. The speech was slow, awkward, and blurred, but no syllables were missed and there was no aphasia. The special senses were normal, there being no optic atrophy. The eyes moved consensually in all directions with a slight tremor on extreme deviation. The pupils were equal and of normal size; they reacted feebly to light and normally on accommodation. There was no anæsthesia of the face and the muscles of the jaw were normal. In repose the face was rather vacuous and expressionless, but on being addressed his face lighted up. The frontalis and orbicularis muscles acted equally and well; voluntary action of the zygomatic muscles was unequal, being more marked on the left side. When smiling the right side of the mouth always moved before and more strongly than the left. The palate was normal. The tongue was not atrophic; it deviated to the right and its movements were spastic. There was some general slight weakness of the right arm; this was especially marked peripherally in the finer movements of the hand which were all stiff and awkward. The movements of the left arm were imperfect but power was good. The respiratory movements were more marked on the right side both above and below. The abdominal muscles all moved well but were a little spastic. There was considerable rigidity of the legs, rather more marked on the right side than on the left; in the left leg there was slight atrophy of all the muscles below the knee. The muscles of both legs were weak but those of the left leg much more so than those of the right. The muscle sense was very deficient in the left leg but was normal elsewhere. The left ankle-joint was much swollen and the foot was displaced. The malleoli were greatly thickened and the distance between them was increased. The astragalus also showed thickening, as did the ligaments and the synovial membrane of the ankle-joint. There was slight excess of fluid in the joint. No osteophytes could be felt. The foot as a whole was displaced outwards and the sole was markedly everted. The ankle could not be flexed to a right angle but it allowed of full extension. The foot could be inverted normally and everted to much beyond the normal. Manipulation of the foot caused no pain and there was no tenderness. On passive movement some bony crepitus could be felt. No other joints were affected. The arm-jerks were all brisk, the right being more so than the left. The right abdominal reflex was absent and the left was diminished. The right knee-jerk was much increased; the left was also somewhat increased. There was slight ankle clonus on the right side but none on the left. The left ankle-jerk was present. The right plantar reflex was typically extensor and the left was extensor with sharp response. Micturition was precipitate but there was no incontinence. Defæcation was normal.

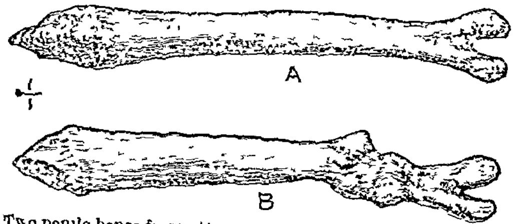
As regards the ankle-joint there can be little doubt that it was of the type of arthropathy described by Charcot in certain nervous diseases. The disease affected a single large joint came on suddenly without signs of acute inflammation and without marked pain, and at the time when the case came under observation there was great structural change in the osseous and ligamentous components of the joint, which was much enlarged and greatly deformed and yet was free from pain and tenderness. The chief point of interest was to determine what was the nervous disease underlying the affection of the ankle. The commonest diseases which are associated with Charcot's disease of the joints are tabes, multiple neuritis, and syringomyelia, but a careful examination of the patient sufficed to exclude the presence of these conditions. Clearly the hemiplegia was not a direct causal factor in the joint change, for the paralysis had been confined to the right side, whilst the affected joint was on the left. The patient gave a history of progressive mental impairment, shooting pains, and precipitate micturition, and on examination there were found Argyll-Robertson pupil and besides the signs of old hemiplegia some evidence of generalised spasticity. These occurring in a patient who has suffered from syphilis suggest a diffuse cerebral degeneration such as characterises general paralysis of the insane.

Birmingham.

FRACTURE OF THE OS PENIS IN OTTERS.

By J. BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS AT THE MIDDLESEX HOSPITAL.

THE otter (*Lutra vulgaris*), like so many other mammals belonging to the order carnivora, possesses a bone in its penis. This bone (represented of natural size in the accompanying illustration) is situated at the end of the penis and the two divergent terminal knobs are invested with the reflexion of the prepuce which covers the glans; the termination of the urethra emerges in the interspace of what may, for convenience, be called the terminal condyles of the bone. The penile bone of the otter is extremely hard and Mr. Gerald Uthwatt, who is keenly interested in otters and in hunting them, assures me that it is not uncommon to find examples of this bone which have been broken and healed. He further supported his statement by sending me a specimen. It is difficult to account for such a fracture unless one knows the habits of otters. It appears that when these animals fight each tries to seize the penis of its adversary and when we remember what powerful jaws and sharp teeth otters possess



Two penile bones from otters. A, The normal bone. B, One that has sustained a fracture and has united soundly.

the damage to the bone is not a matter for surprise. The normal bone and the damaged, but repaired, specimen are in the museum of the Royal College of Surgeons of England.

Reviews and Notices of Books.

Diseases of the Liver, Gall-bladder, and Bile-ducts. By H. D. ROLLESTON, M.A., M.D. Cantab., F.R.C.P. Lond., Physician to St. George's Hospital, London; formerly Examiner in Medicine in the University of Durham; and Fellow of St. John's College, Cambridge, England. Philadelphia, New York, and London: W. B. Saunders and Company. 1905. Pp. 794, with 97 figures in the text and seven coloured plates. Price 25*s.* net.

As a work of reference on the subjects dealt with in it Dr. Rolleston's book leaves little to be desired. It is conveniently arranged and easy of reference, the symptoms are in all cases well described, the morbid anatomy and pathology of the various conditions are exhaustively discussed in a luminous and critical manner, while diagnosis and treatment are given in considerable detail. The work is enriched by abundant brief descriptions of illustrative cases, many of them from the author's own personal experience, and in each case with reference to the literature. Dr. Rolleston has wisely refrained from adding a long bibliography to his volume but gives at the foot of each page references to the authorities quoted in it, a much more useful method in a work of reference. As might be expected from a physician of Dr. Rolleston's wide pathological experience, the morbid changes observed in each condition are very carefully described, often with great detail, and are illustrated by a large number of excellent figures, microphotographs, and coloured plates, for, as Dr. Rolleston observes in his preface, "without a grasp of these (morbid changes) it is impossible to make a rational diagnosis, to treat the clinical manifestations in a satisfactory manner, or to give a reliable prognosis." In his discussion of the pathology of many obscure conditions Dr. Rolleston is always interesting and frequently original and suggestive in his ideas. He rightly attributes great importance to the antitoxic or protective function of the liver—that is, its power of arresting poisons absorbed from the alimentary canal, or at least of rendering them innocuous, and to "hepatic insufficiency" or interference with this function he attributes many of the symptoms of hepatic diseases, notably in cirrhosis and complete biliary obstruction.

In reviewing a work of such magnitude it is impossible to do more than refer to some of the principal sections. Excellent accounts are given of the condition of emphysematous or "foaming liver," of the corset liver, and of wandering liver or hepatoptosis. An important chapter is devoted to the discussion of functional disease of the liver. Disturbances of hepatic functions are admittedly common in hepatic disease but the question of the existence of a primary functional disorder of the liver is still unsettled, and Dr. Rolleston sums up by stating that "in the present state of our knowledge its existence is almost impossible to recognise with accuracy." Diseases of the vessels of the liver are considered in some detail, including thrombosis of the portal vein and suppurative pylephlebitis, which is considered separately from portal pyæmia or multiple embolism from the portal vein radicles. In his discussion of chronic venous congestion of the liver or "nutmeg liver" we are glad to find that Dr. Rolleston doubts the existence of a "cardiac cirrhosis" and regards the fibrous tissue found in such cases as a secondary fibrous replacement following the atrophy of the liver cells in the central part of the lobule.

Acute congestion of the liver, acute hepatitis, and tropical abscess are described and differentiated from one another. In the account of tropical abscess its relation to dysentery and the part played by the amœba coli in its pathogenesis are included and a hæmatogenous origin is suggested for some of the pulmonary abscesses found complicating hepatic abscesses, since amœbæ have been found in the pulmonary artery.

The account given of universal chronic perihepatitis lays great stress on the frequency of its association with arteriosclerosis and granular kidneys, and the rarity of its association with true cirrhosis of the liver. The distinction between this condition and that of cirrhosis so ably worked out by Dr. W. Hale White is clearly defined.

The section dealing with cirrhosis is very exhaustive, extending to over 160 pages, and is one of the best parts of the work. A classification of cases of cirrhosis capable of being used in practice is much to be desired, since the anatomical classification into multilobular, monolobular, pericellular, mixed and sporadic given by Dr. Rolleston is, as he himself points out, chiefly of pathological interest. For clinical purposes he describes two principal types—(1) ordinary or common portal cirrhosis with hæmatemesis early in its course and ascites late, and with multilobular fibrosis of the liver and only moderate enlargement of the spleen; and (2) the biliary type with jaundice for its most marked feature, both liver and spleen being very large and the fibrosis in the former being mixed, diffuse, or monolobular.

In discussing the rôle of alcohol Dr. Rolleston comes to the conclusion that it "gives rise to cirrhosis in a secondary manner either by leading to the production of sclerogenic poisons or by enabling such poisons to have full sway on the liver," and that other factors must also be taken into account, since alcohol *per se* simply leads to fatty degeneration. Again, the possibility of cirrhosis, or at any rate some forms of cirrhosis, being due to micro-organisms must always be borne in mind, as also that poisons and perhaps micro-organisms may reach the liver by the hepatic artery or in the fœtus by the umbilical vein. Many of the symptoms, Dr. Rolleston suggests, may be due to hepatic insufficiency—notably some of the hæmorrhages, the ascites, the dropsy, and the final toxæmia. The processes of compensation, especially the new formation of the hepatic cells forming what Dr. Rolleston calls the pseudo-bile canaliculi and the collateral circulation between the portal and systemic venous systems, are described and the indications for, and limitations of, the Talma-Morison operation are discussed in some detail. Dr. Rolleston is of opinion that this collateral circulation may become too free and so permit the circulation of toxic substances absorbed from the intestines without allowing them to be dealt with first in the liver. The account of biliary cirrhosis is a useful summary of what is at present known about that comparatively uncommon disease. The name is perhaps an unfortunate one but has become firmly established and is preferable to the ambiguous term hypertrophic cirrhosis sometimes applied to it.

The sections on tubercle, syphilis, and malignant disease of the liver are each of them exhaustive; that on actinomycosis or streptothricosis is, however, less detailed. In the account of congenital syphilis we are glad to find an account of what Dr. Rolleston calls parasyphilitic cirrhosis—that is, a polylobular cirrhosis occurring in syphilitic children induced by other causes—an important condition which has hitherto attracted very little notice. Diseases of the gall-bladder and bile-ducts form the concluding sections of the volume and are carefully and systematically described. The part played by catarrhal and infective processes in the production of gall-stones is carefully considered in the section on cholelithiasis.

A few typographical errors have escaped correction and the adjective "tuberclic" used on p. 191 does not commend itself to us but the book is well written and well produced and we can cordially recommend it as a work of reference containing a mine of valuable information and of suggestive ideas.

Diseases of the Blood (Nothnagel's Encyclopedia of Practical Medicine; English edition). By Professor Dr. P. EHRLICH, Professor K. VON NOORDEN, Dr. A. LAZARUS, and Dr. F. PINKUS. Edited, with additions, by ALFRED STENGEL, M.D., Professor of Clinical Medicine in the University of Pennsylvania. Philadelphia and London: W. B. Saunders and Co. 1905. Pp. 714. *Price 21s. net.*

THE present volume of the American edition—for although it is called the English edition it is written in the American dialect—of Nothnagel's well-known Encyclopædia suffers perhaps more than most of those already issued from the conditions under which it is produced—the re-editing of a series of important monographs after the lapse of a certain period of time, combined with the attempt to introduce into the text an account of researches carried out in the interval. Our knowledge of the pathology of the various conditions signalised by changes in the composition of the blood is at present in a very rudimentary state, in spite of the immense amount of labour which has been expended in attempts to elucidate the problems involved. The work of Professor Ehrlich and his pupils has done much to lay a foundation upon which to build, but many of the views put forward by these observers have failed to command universal consent and the tendency of recent work has been on the whole rather antagonistic. Hence the attempt of the editor of the present translation to incorporate the results of later researches with the original articles has been unusually difficult and the result is to produce a somewhat confusing impression on the mind of the reader. It is, indeed, easier to indicate what we do not know than what we do know with regard to the physiology and the pathology of the blood. We do not know the life-history of the red or of the white corpuscles with any approach to accuracy. The source of the erythrocytes in the bone marrow is fairly well ascertained but as to their length of life and their seat of destruction we are quite ignorant. Evidence is accumulating to show that the marrow is one of the birthplaces of the leucocytes, but some of these cells almost certainly originate in the lymphatic glands, while the relations of one form of leucocyte to another are still a matter of controversy. The functions of the spleen are equally undetermined, though it has been clearly proved that this organ is not essential for life. In such circumstances it is not surprising that diseases of the blood form an ill-understood group of affections.

The volume before us opens with an account of the normal and pathological histology of the blood, written by Professor Ehrlich and Dr. Lazarus. This is followed by sections upon Secondary Anæmia, the result of hæmorrhage, and upon Pernicious Anæmia, by Dr. Lazarus alone. In the account of the latter much is made of the existence of megalocytes (large red corpuscles) as the distinguishing feature of the disease. The well-known excess of hæmoglobin as compared with the number of corpuscles is explained as due to the size of the latter. As defined in this article pernicious anæmia is clearly not a single "disease," since the form of anæmia due to the bothriocephalus latus is definitely included under the term. It seems fairly clear that this parasite acts by means of a toxin, and as the blood-picture is practically the same in the ordinary form of pernicious anæmia it is natural to conclude that it, too, is toxic in origin. But of the nature of the poison in so-called "idiopathic" cases nothing certain has been discovered. Some of the features of the disease, such as the diminution in the number of the leucocytes and the ulcers which in some instances affect the Peyer's patches of the intestine, seem to point to an action closely resembling that of the typhoid toxin.

The article on Chlorosis is written by Professor von Noorden and is, from a practical point of view, the best in the volume. The treatment of the condition is very fully described. The author's views as to the origin of chlorosis in a defect of an internal secretion which should be furnished by the ovary are well known and form one of the most interesting speculations as to the cause of this affection; it must, however, be recognised that it is only by excluding certain cases occurring in the male sex, which exactly resemble chlorosis in clinical features, that such a theory can be upheld. Professor von Noorden considers that the function of the ovarian secretion is to stimulate the action of the bone marrow in forming red corpuscles and that the therapeutic effect of iron is due to its supplying an alternative stimulus.

If little is known of chlorosis and of pernicious anæmia, still less would seem to have been ascertained with respect to the pathology of leukæmia. In the book before us the usual division into lymphatic leukæmia or lymphocythæmia and myeloid or spleno-medullary leukæmia is maintained. The former is divided into acute and chronic forms, and pseudo-leukæmia, better known in this country as lymphadenoma or Hodgkin's disease, is included under this heading. It is noteworthy that in acute leukæmia there usually occur a considerable number of large uni-nuclear leucocytes, here classed as large lymphocytes, which are not very sharply distinguished from the hyaline or myeloid leucocytes characteristic of spleno-medullary leukæmia. We must be content at present to admit that the classification of these maladies is as unsatisfactory as their pathology. Together with the curious condition called chloroma they form a group of allied affections, but the relations of the members of the group to one another and to other diseases such as sarcoma are quite undetermined.

On the whole we may say that this work offers much valuable information to all who are specially interested in conditions of the blood. The bibliography appended to the articles is very complete and the editor's additions bring the matter well up to date. It is hardly a book which will appeal to the busy practitioner or to the student, since with the exception already noted treatment is not a strong feature, while the obscurity of the subjects dealt with admits of no clear dogmatic conclusions being reached. There are a good many misprints scattered about in addition to certain unusual forms of words, such as "abolishment," "unexceptionally" (for "invariably"), and phrases such as "a few swallows of wine," or "The author had Rethers publish......," which we must regard as Americanisms. The following sentence seems somewhat involved: "That they [nucleated corpuscles] suddenly appear in large numbers in a similar manner to the 'blood-crises' first described by *the authors*, as Neudorfer mentions, *the former has* never seen in spite of diligent investigation, although *we has* seen this quite frequently in other forms of anæmia." The italics are ours. In general the translation is moderately well done. There are some good illustrations of blood conditions.

Manual of Antenatal Pathology and Hygiene: The Embryo. By J. W. BALLANTYNE, M.D., F.R.C.P. Edin., F.R.S. Edin. Edinburgh: William Green and Sons. 1904. Royal 8vo, pp. 697. *Price 21s. net.*

THE first volume of this manual dealt with the diseases of the fœtus; the second is concerned with the pathology of the embryo and with a short sketch of the morbid processes which may be initiated or determined in germinal life. As Dr. Ballantyne points out, the pathology of the embryo is synonymous with the subject of teratology, or at least with that part of it which deals with single as opposed to double monsters. One of the main features of the present volume is that in it the author has dealt very fully indeed with the subject from the side of causation, and it represents the first connected attempt to deal with the genetic aspect of abnormal formations. In any consideration of the pathology of the embryo it is necessary first to consider its physiology, as only in this way can a clear conception of the nature of the morbid processes affecting it be obtained. The physiology of the embryo differs very markedly from that of the fœtus, since to obtain a clear idea of it we must think of the organs not as performing any functions but as in process of formation. The only function of the embryo is organogenesis, and there can be no anatomy of the embryo apart from its physiology. As a necessary corollary of this statement the chief effect of pathological processes on the embryo is the malformation of its organs. At the same time it must be remembered that all that is teratological does not of necessity belong to the embryonic period; thus some malformations undoubtedly arise in the fœtal period of life and united twins, for instance, are probably determined in the germinal period of ante-natal life.

If the abnormal development of the embryo or its teratology is to be understood then a start must be made with a study of its normal development or embryology. Inasmuch, however, as human embryology is incomplete, so our knowledge of human teratology must also be incomplete. As a necessary preliminary therefore, Dr. Ballantyne, after pointing out these facts in the first chapter of this work, devotes the next five chapters to a sketch of the most important facts of human embryology. By this term he means the science which treats of the origin and formation of the parts and organs of the embryo; and it includes a study of all the changes through which the embryo passes from the appearance of its first rudiments up to the transformation of the "transition organism" into the recognisably human embryo. In the section on the general principles of embryology Dr. Ballantyne points out very clearly the many difficulties which beset us when we endeavour to form some idea of the nature of the various processes and of the series of changes in the development of the embryo to which the term ontogenesis is usually applied. As he truly remarks, a fact which many writers have forgotten, there is a specificness in the ontogenesis of different types of animals, and that the embryo of the chick differs in very many particulars from that of the mammal cannot be too clearly remembered. Further than this, a great principle to be always borne in mind in our studies of embryological and teratological processes is the so-called principle of biogenesis, or the fact that ontogenesis never follows a simple or direct route but reaches its end by detours, and, lastly, that ontogeny does not give an epitomised recapitulation of evolutionary progress, it is not therefore an epitomised phylogeny. In an attempt to describe the period of antenatal existence, which extends from the appearance of the first rudiments of the embryo up to its transformation into the neofœtus, we are at once met with the difficulty as to when may it be said that the embryonic life of the new organism begins. As a probable conjecture Dr. Ballantyne supposes that three and a half days after coitus impregnation occurs and that one week later embryonic existence commences with the appearance of the first rudiments of the embryo and that it ceases at the end of the sixth week when the embryo assumes a human appearance. In the third to the sixth chapter he considers this period of development. Having completed in this way a short sketch of embryology in order he is then in a position to pass on to a consideration of embryology in disorder or teratology.

In the seventh chapter the general principles of the pathology of the fœtus are dealt with and it is pointed out that their peculiarities may be regarded as determined by the special physiological conditions of the embryonic period of life and by the transmission into embryonic life of morbid states acquired in the germinal period. The three most important factors to be considered are the physiological, the amniotic, and the germinal; for just as morbid causes in fœtal life act chiefly through the placenta so similar causes in embryonic life act chiefly through the amnion. The environment of the embryo is represented by the amnion and while the physiological factor and the amniotic factor serve to explain most of the phenomena of teratology, yet there are some still to be explained and possibly the solution of the problem lies in the germinal factor. In the next three chapters the various theories of the causation of monsters are considered or the subject of teratogenesis. A full description of the many theories of the past are given, including the supernatural and the natural, and then the author passes on to a discussion of the mental causes or the belief in the influence of the maternal or paternal imagination in the production of monstrosities. There is a very good account of this theory as it has prevailed from the very earliest times up to the present day and, as Dr. Ballantyne truly says, it is extraordinary whether its truth be affirmed or denied and wonderful both in its wide extension in space and time, and in its firm hold both on the minds of the profession and the laity. That it has had a baneful effect upon the progress of antenatal pathology there can be no doubt but whether it is true or not is a matter yet unsettled.

Does a definite impression upon a pregnant woman's mind ever or often cause a defect in the fœtus closely resembling the thing producing the impression? Has the state of the mother's mind any effect on the unborn infant's development? The first question Dr. Ballantyne answers in the negative and the second affirmatively. While he is prepared to admit that the mother's nervous system is often in a peculiar state during pregnancy, yet he regards it as impossible that the sight of a mutilated individual can be so transmitted mentally by the mother as to cause a fœtal amputation resulting in a similar deformity in utero. That strongly marked mental states of the mother may affect the development of the fœtus in utero he admits and to this extent he believes in the old doctrine of maternal impressions. It must be remembered that the results of such mental states are not always necessarily teratological but may be seen in the production of sterility, abortion, congenital debility, or retarded growth.

While some of the teratogenic theories of the past are represented by modern developments, so some of the present-day views spring from very ancient notions indeed. The idea that antenatal deformities may be due to causes acting mechanically on the fœtus is to be found in the writings of Hippocrates and it is one of the most important theories of the present time. In considering it we must remember that the pressure theories are of many kinds and that the form of pressure varies equally widely in the writings of different authors. For this reason Dr. Ballantyne considers the subject under the two heads of pressure exerted upon the fœtus from the outside or from the inside of the mother's abdomen. The question of amniotic pressure is placed under the head of disease as a cause of fœtal monstrosities. The view that diseases are the cause of deformities or the nosological theory of teratogenesis may be regarded from two standpoints: first, that it is diseases of the fœtus itself which are the cause of the deformities; and secondly, that it is through disease of the fœtal membranes, and especially the amnion, that these anomalous conditions are set up. The three different ways in which the amnion may produce fœtal deformities—viz., by disease, by pressure, or by arrested development—are all discussed at considerable length, and, as Dr. Ballantyne justly says, our conceptions of the manner in which the amnion acts must be modified to some extent in view of the recently ascertained facts as to its development. Its presence fully formed in the earliest human ovum yet described indicates that it may be capable of performing functions at a date before the embryo has passed through the formative or embryonic stage and that it may be quite accurate therefore to speak of disease of the amnion as a cause of deformities, as well as its defective development and the pressure thus produced upon the plastic embryo.

The last theory which has to be considered is the embryological one and in association with this there is a most excellent summary of the work done by many observers in the domain of experimental teratology. What part is played by the action of various poisons and toxins in producing defects in the amnion and whether or not some monstrosities such as those of excess and the double monsters are not due to morbid causes acting upon the blastoderm or even upon the ovum or the spermatozoon before or during impregnation remains yet to be determined. In the classification of monsters the author has adopted one founded upon that selected by Taruffi in his well-known "Storia della Teratologia." In this classification all teratological phenomena are divided into two main divisions, the monosomatous terata in which only a single individual is involved and the polysomatous terata in which two individuals (or at least something more than one) are involved. The greater part of the remainder of the volume is devoted to a description of the various types of monsters. These chapters, based as they are upon the author's unrivalled knowledge of the literature and his exceptional experience of actual specimens, are models of completeness and scientific accuracy and teem with numerous facts and speculations. The last three chapters, perhaps the most interesting in the book, are concerned with a sketch of the pathology of the germ. Dr. Ballantyne aptly names this unknown field the hinterland of antenatal pathology. Our knowledge of it is of the scantiest and our means of improving it are of the slightest. For those who wish to obtain some idea of what is known of this subject, including as it does the vexed questions of the origin of double monsters and of morbid heredity, we can recommend a study of these most fascinating chapters.

In finishing our sketch of this important work we cannot help regretting that Dr. Ballantyne has not been able to carry out his original intention of treating the pathology of the germ in the same complete way as he has that of the fœtus and the embryo. The work would have been one of great value and interest and the three volumes would have formed a trio well worthy of the high reputation of their author. This volume forms a fitting sequel to the first and it only remains for us to congratulate Dr. Ballantyne on the production of a work which stands quite unrivalled in this branch of medical science and which is a credit to him and to the school of medicine to which he belongs.

LIBRARY TABLE.

Nursing in Eye, Ear, Nose, and Throat Diseases. By A. EDWARD DAVIS, A.M., M.D., Professor of Diseases of the Eye in the New York Post-Graduate Medical School and Hospital; and BEAMAN DOUGLASS, M.D., Professor of Diseases of the Nose and Throat in the New York Post-Graduate Medical School and Hospital. With 32 illustrations. Philadelphia: F. A. Davis Co. 1905. Pp. 318. Price $1.25 net.—This little book is sensibly written by competent men and is well adapted for those whom it is intended to instruct—nurses, students, and those general practitioners who have not had the time or the opportunity in their student days of attending or holding office in ophthalmic wards or in those devoted to the ear, nose, and throat. The importance of sterilisation of all instruments and dressings is, of course, dwelt upon by both authors. Dr. Davis especially guards his readers against the employment of any of the quack nostrums so frequently recommended by unprofessional people for what is commonly regarded as a "cold in the eyes," a condition that may mean anything, as Dr. Davis says, from a cinder on the cornea to the most virulent cases of diphtheritic conjunctivitis. The method of applying a Buller's shield is well given. Wet poultices of all kinds are condemned, but we do not notice any recommendation of a remedy that is sometimes of great value—dry heat, applied in the form of a bag of chamomile flowers in cases of chronic inflammation of the sclera, cornea, or other tunics of the eye. Dr. Davis employs a 10 per cent. solution of nitrate of silver in the early stages of purulent ophthalmia, and of the more recently introduced preparations of silver he prefers argyrol, which in such cases should be of the strength of 250 grains to the ounce. He rightly cautions the practitioner against using the peroxide of hydrogen in cases of croupous and diphtheritic conjunctivitis. Whether the employment of jequirity bean dust by either nurse or practitioner is ever advisable may be considered more than doubtful. It is a dangerous remedy in unskilful hands. The modes in which various remedies that are in common use should be applied to the eye are, of course, fully given, with brief notices of their effects. Massage of the eye, it is observed, is sometimes practised, the chief affections in which it has been found serviceable being blepharitis, chronic conjunctivitis, ecchymosis of the lids and conjunctiva after blows, twitching of the orbicularis, and phlyctenular ophthalmia. It is stated to be useful in cases of non-inflammatory glaucoma but in view of the difficulties of diagnosis in such cases it seems hardly a fit remedy to be recommended to a nurse. Dr. Douglass's section emphasises the importance of cleanliness and gives the following as the procedure practised by many of the surgeons at the New York Post-Graduate Hospital. "1. The hands and arms are first thoroughly scrubbed with soap and water with a brush. 2 Dipped into alcohol (95 per cent.) for one minute. 3. Dipped into permanganate of potash solution (2 per cent.) for from three to five minutes. 4. Bleached in a saturated solution of oxalic acid until all the stain from the permanganate is gone. 5. Dipped into a solution of bichloride of mercury (1 in 1000) for one minute. The hands are then dried with a sterilised towel." The reader will find well-written sections on nursing in mastoid cases, the modes of arresting nasal hæmorrhage, and the diet after operations on the nose and the throat.

JOURNALS AND MAGAZINES.

The Medical Magazine.—The issue for June contains a good account of papers read at the recent Conference on School Hygiene and is consequently of more than ordinary value to all interested in that subject. The matter is approached from various sides, amongst others by Dr. A. K. Chalmers, dealing largely with the question of school children's diet and clothing, while Dr. Arthur Newsholme's remarks refer principally to the question of infections and their avoidance. The presidential address by Sir Arthur Rücker considers the two opposing views of the pro- and anti-classics educationists and touches on the ever-present examination question. This number of the magazine has, further, an excellent article on the Operations for Cure of Prostatic Enlargement by Mr. John G. Pardoe.

The Practitioner.—A clinico-physiological article upon the Breathlessness of Cardiac Origin from the pen of Sir Lauder Brunton opens a very good June number of this periodical. Dr. R. Saundby writes upon Cirrhosis of the Liver. In considering the flatulence that often accompanies cirrhosis he lays a stress that appears to us out of proportion upon the part played by atmospheric air swallowed during the taking of food. The prize essay of the month, on the Causation of Appendicitis, comes from Dr. F. C. Bottomley and is a capital little *résumé* of the subject. Mr. J. W. Thomson Walker gives a good account of recent methods of diagnosis in renal surgery.

The Royal London Ophthalmic Hospital Reports. Edited by WILLIAM LANG, F.R.C.S. Eng. London: J. and A. Churchill. Vol. XVI., Part I. June, 1905. Price 5*s*.—The articles contained in this number of the Ophthalmic Hospital Reports are the following: 1. On Renal Retinitis in Young Subjects and on the Relative Frequency of Juvenile Interstitial Nephritis in the Two Sexes, by E. Nettleship. 2. Observations on the Prognostic and Diagnostic Value of Retinitis in Diabetes, by E. Nettleship. Mr. Nettleship finds that the prognostic importance of the retinal changes in chronic renal disease in children is not less grave than in adults. Renal retinitis occurs almost twice as frequently in females as in males. He finds also that the retinal alterations in diabetes are less marked than in renal retinitis. Death results from the diabetes. 3. Primary Chancre of the Conjunctiva and Interstitial Keratitis, by E. Treacher Collins. 4. The Innervation of the Pupil, by J. Herbert Parsons, Curator of the Royal London Hospital Museum. In this article the numerous and various opinions that have been advanced in regard to the action of nerves on the movements of the iris are collected and it closes with an excellent bibliography. 5. Thrombosis of the Central Vein of the Retina, by George Coats. Mr. Coats gives the details of four cases which he has had the opportunity of observing microscopically. The article is an important one and is illustrated by plates showing the appearances seen.

New Inventions.

AN OPHTHALMOSCOPE.

RECENTLY I showed before the Ophthalmological Society a new ophthalmoscope made for me by Messrs. Weiss and Son of London. The instruments at present in use are so good that it would be an impertinence to suggest that they were capable of modification. That which I have designed is something quite different from any existing machine, so it has at least the merit of novelty. Fig. 2 shows the back of the instrument. There is a sight hole with indicators above and below it; that above the sight hole registers tens of dioptres, that below units. When the driving wheel is turned in either direction all the whole numbers of 70 consecutive dioptres pass beneath the sight hole. The range for concave lenses is from 39 dioptres to 1 dioptre, for convex lenses from 30 dioptres to 1 dioptre; there is of course a blank in proper place in the series. Despite this great range of dioptres there are only 15 actual glass lenses in the instrument. There are two discs or wheels carrying lenses which overlap at the sight hole. The larger or units-wheel is geared into the driving wheel and has ten holes; one is blank, and nine are glazed from –1 D. to –9 D. At one point of the rim of this units-wheel there is a finger-like projection. The smaller or tens-wheel has seven holes; one is blank, the others are glazed with +10, +20, +30, –30, –20, –10 dioptres: the blank lies between the two 10 D. lenses, and the two 30 D. lenses are beside each other. This tens-wheel has fixed to one face a spur-wheel of seven teeth; it is quite free from contact with the units-wheel except when the revolution of the units-wheel brings the finger-like projection on its rim upwards in line with the axis of the instrument, then this finger engages a tooth on the tens-wheel and pushes that wheel round one point—a seventh of its circuit. The tens-wheel is governed by a cam so that it only moves one point at a time and always stops accurately centred. The finger on the units-wheel is between 9 D. and O, so when this wheel is revolved as 9 D. disappears from the indicator and before O appears the next tens-lens in the series is automatically brought into position; the movement is repeated as the driving wheel is turned in either direction ad infinitum. It will be noticed that all the unit lenses are concave, whilst the tens lenses are both concave and convex; it follows that the dioptric value at the sight hole at any point is the algebraic sum of the two figures appearing in the indicators above and below the sight hole. The denominating numbers are engraved on the metal which carries the lenses and cannot be displaced, as is usual in England, convex lenses are marked with red indicators and concave with white. This mechanism I have utilised is known as the "Jumping indicator" and was invented by Harding, an engineer of Leeds, about 30 years ago. It is almost human in its working and has been successfully applied to numerous speed indicators for ships cycles and carriages, turnstiles, meters and chronographs There is no doubt about its stability and reliability, whils the movement is so "sweet" (to use the engineer's term) that it is hardly possible to tell by the touch when the tens-wheel is being moved. For rapidly setting the lenses at any desired point of the 70 D. range there is provision for driving the tens-wheel directly by a touch of the finger. The mirror arrangement is new; it is a combination of the rotatory mirror, the reversible double mirror, and of Loring's tilting mirror. There are plane and concave mirrors placed back to back, so arranged that they are capable of universal movement and tilting, and are equally available for direct or indirect examination of the eye or retinoscopy. By an "embrasure" form of sight hole the tunnel through the mirrors and their septum is reduced to the thickness of a single mirror, to the great advantage of the observer; further the mirrors are so hung that they are never flatly applied to the instrument; therefore it is almost impossible to break them by any of the ordinary accidents an ophthalmoscope is liable to, short of crushing violence. The driving wheel has been made of a large and convenient size and is fitted with a pupillometer and scotometer for the testing of colour vision A steel loop-shaped handle is part of the instrument and folds by a spring hinge; when it is folded it surrounds the mirrors and protects them, so that a case is not an absolute necessity When closed the ophthalmoscope measures only 3⅛ inches by 1¼ inches by ⅜ inch; its weight, including case, is under two and a half ounces. It is therefore the smallest complete refraction ophthalmoscope yet devised.

Queen Anne-street, W.

MOUNT VERNON HOSPITAL FOR CONSUMPTION, NORTHWOOD.

THE country branch of the Mount Vernon Hospital for Consumption has now been in actual working order for some months and about 60 patients are constantly under treatment. We therefore willingly availed ourselves of an opportunity of visiting the sanatorium and of inspecting the various buildings of which it is composed. The sanatorium was designed by Mr. Frederick Wheeler, F.R.I.B.A., and is situated upon an estate of 104 acres near Batchworth Heath, Middlesex, a distance of some 16 miles from London. The site is 375 feet above sea level, the soil being sand and gravel overlying chalk. The hospital is built on a southern slope and provides for the treatment of 114 patients (57 male and 7 female) and consists of eight separate buildings which are connected by means of covered ways. We reproduce a plan (Fig. 1) which shows the relative positions of the component parts of the sanatorium. The provision of such covered ways is highly commendable, for there are numerous objections to having the kitchens, laundry, nurses' apartments, and so on, entirely cut off from the wings in which the wards for the patients are contained.

The largest and most important of the buildings is Block A (Fig. 1) which may be termed the hospital proper. It consists of a central block of three storeys, having a central tower, with the wards arranged in extended wings on either side. This building has a south aspect and its length is 500 feet, the wings being placed at a slight angle. In the central portion of this block is situated the principal staircase. The ground floor comprises two consulting rooms, the dispensary staff dining room, and the private apartments of the resident medical officer and matron. Upon the first floor are the library and two reading rooms (for men and women respectively). The library is rightly not accessible to the patients but the books are passed through hatchways into the reading rooms. On the upper floor of this central block accommodation is provided for the hospital servants who each occupy a separate bedroom. On the north side of each wing and running throughout its entire length is a well-lighted and ventilated main corridor, nine feet wide, paved with marble terrazzo and having a green brick dado, presenting a very pleasing appearance. Opening from this corridor there are on the ground floor in each wing three large wards for ten beds each and three wards containing single beds. The wards have a cubic space of not less than 1400 feet per bed. They are lighted by large French casement windows which open, in the case of the ground floor wards, on to a broad terrace extending along the whole south front of the hospital. Similar windows in the wards above open on to a balcony which also extends along the whole south front and is set back several feet in order not to interfere with the light and circulation of air on the terrace below. These ward windows are fitted with latticed roller blinds which form a good protection against wind and rain. Further ventilation is provided by means of hopper-hung windows placed high up on the corridor side of the wards. Abundant access of fresh air is thus afforded. The walls of all the wards are treated with distemper above dadoes which are finished with Ripolin paint and the angles are, of course, everywhere rounded. An excellent plan of heating has been designed by placing in the centre of each ward a specially arranged Teale stove with double fire-places. We were informed that this method answers admirably.

In addition to the wards already described there are four isolation wards situated in spurs connected with the main corridors by cross-ventilated passages. They can be entirely shut off from the main wings and have separate external entrances. In connexion with each are provided a nurse's kitchen and lavatory. This arrangement is most complete and will be found valuable in cases of unexpected developments in the way of infectious diseases or complications necessitating the isolation of patients. In having wards containing several beds this sanatorium differs from most of the more modern buildings in which each patient has a separate bedroom. We were favourably impressed with the appearance of the wards. The space allotted is ample, and if a patient is confined to bed the sense of companionship, owing to other patients being in the same room, has certainly something to commend the large-ward system. From a purely theoretical point of view separate bedrooms are to be preferred, and it will be interesting in future years to ascertain whether the use of separate rooms as opposed to wards yields the more favourable statistics.

Connected with the main corridor by means of cross-ventilated passages are the sanitary spurs which are centrally placed on each floor and in each wing and are suitably fitted up with all modern appliances. A nurse's sitting room and kitchen are also provided near the same spurs. In addition to the staircases for patients lifts are provided in each wing. Large winter gardens are placed at the extreme end of each wing and can be entered both from the terrace and from the main corridor. Patients are thus able to obtain exercise in bad weather by walking along the terrace, sheltered by the balcony above, through the winter gardens, along the corridor and back to the terrace again. As there are no wind screens in the grounds this promenade is found very convenient when the patients are unable to use the grounds. On the first floor there is in each wing a recreation room. A piano is placed in each, also a billiard table for the men and a bagatelle table for the women. These recreation rooms are divided from the reading rooms by glazed screens. Advantage has been taken of a fall in the land to construct a subway under the main corridor; the lifts in connexion with the patients' staircases descend to the level of this subway, at the end of which, under the winter garden on the men's side, are placed the pathological and post-mortem rooms. The pathological laboratory is admirably fitted up and provided with appliances for research work. Block B, in which is situated the principal entrance, is the administration building and residence of the honorary physician-in-charge. The administrative department is placed on the ground floor and comprises a large entrance hall, board room, secretary's office, and other necessary rooms. Block C is the patients' dining hall and provides accommodation for about 250 persons. The patients sit at small tables, an arrangement which has several advantages. The hall is well lighted and ventilated but is placed rather too near the main block. The Langfield system of heating has been adopted and there is also a specially designed double Teale stove placed in the centre of the hall. The building is connected with the kitchen (Block E) by a special service corridor in addition to the main covered way. Block E, the kitchen building, is, in view of the anticipated future extension of the hospital, larger than is necessary for the present purposes. The cooking arrangements are well devised and the larder and store accommodation are ample. The milk room contains a 35 gallon steriliser. The nurses' home (Block D) is also arranged in accordance with modern ideas. Each nurse has her own separate bedroom and the night nurses' rooms are shut off from the rest of the rooms, so as to insure quiet during the day. Block F is the stable building where in addition to the usual requirements there is a motor garage for three cars. Block G is a building of considerable size, the laundry and electrical plant being housed therein. The laundry occupies the whole of the first floor of the building and is on a more extensive scale than would be necessary for an institution of this size, for here is carried on the washing not only of the sanatorium but also for the parent hospital at Hampstead. All the linen articles and the like are, of course, disinfected before being washed. It is not necessary for us to give a detailed description of the machinery and methods employed. Suffice it to say that all the arrangements are everything that can be desired and could scarcely be improved either in completeness or efficiency. The hospital is lighted throughout by electricity, the current being supplied from an extensive plant in duplicate, which is housed in the lower portion of Block G. There are three engines which are coupled to three shunt wound dynamos of the multipolar type. The battery is of the "Hart" type, of 116 cells, and having a capacity of 540 ampère hours when discharged at 60 ampères. Connected with Block G is an incinerator wherein are cremated all the house refuse and sputum of the hospital.

The water-supply is obtained from an artesian well which has been specially sunk. The pumping plant, which is placed in Block H, is designed to lift 2500 gallons of water per hour from the bore-hole, about 4500 feet deep, into a receiving tank immediately under the floor of the pump-house and thence to the reservoir tanks in the main building, the

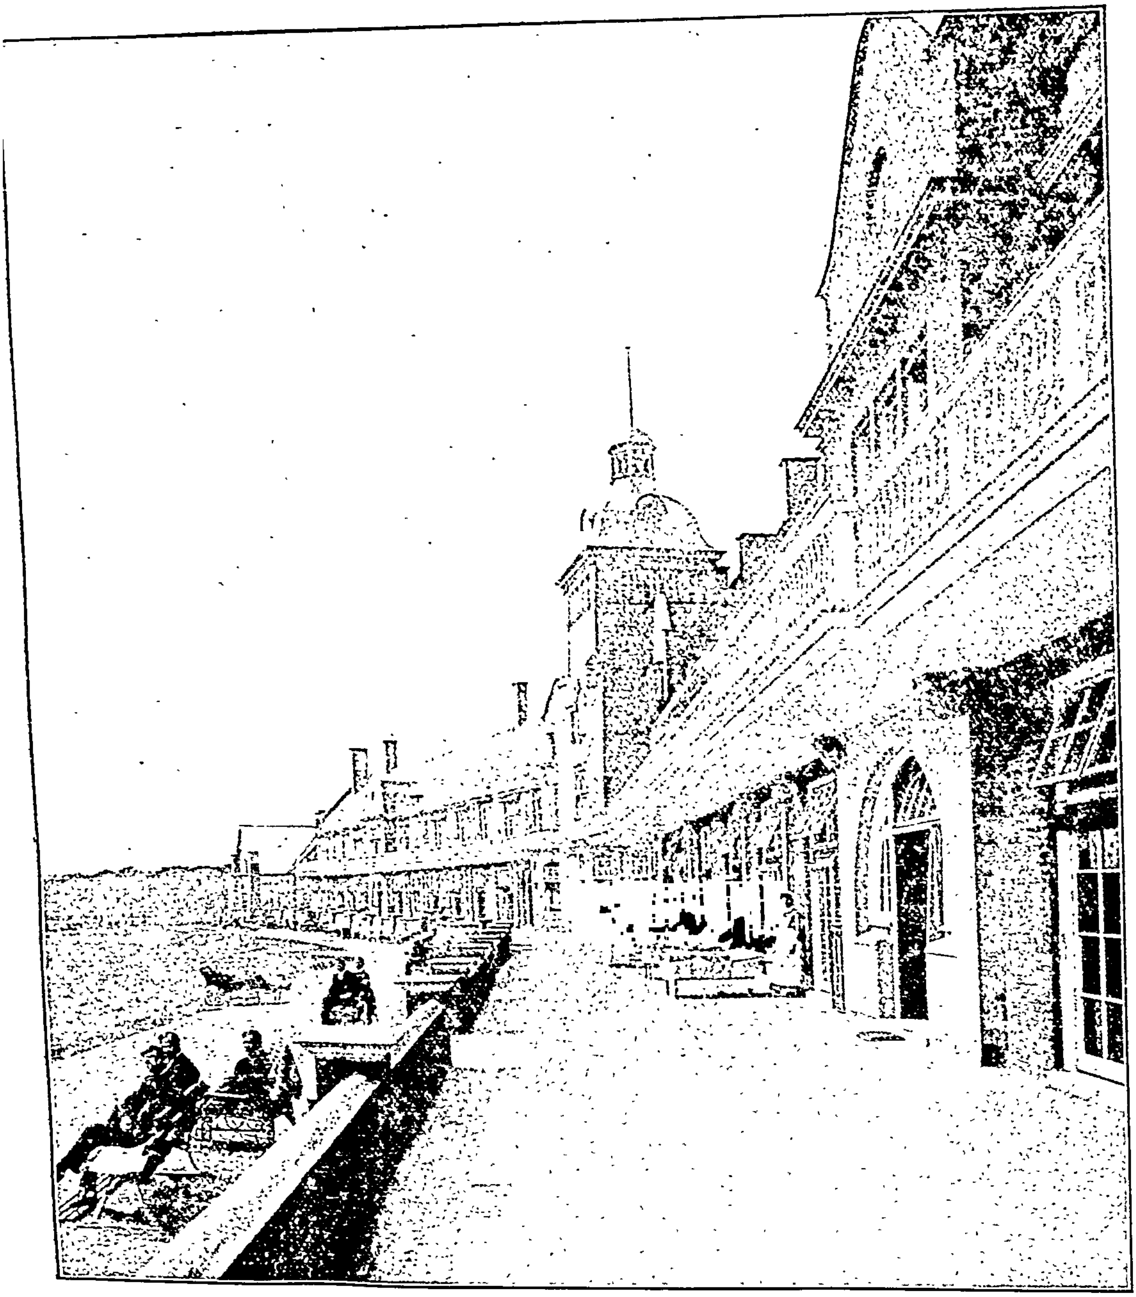
laundry, and other tanks. The provision for assuring a constant supply of hard and soft water is very elaborate and no fear need be experienced of a failure in this department. In case of a breakdown or temporary failure of electrical power arrangements have been made to work the pumps by steam power, in which case they would be connected by means of auxiliary shafting to the steam engines in Block G. The water softening plant is of the "Stanhope" type and is capable of treating 10,000 gallons per day. The only reagent used is lime and the plant includes its own motive gear, the mixing being effected continuously by power taken from a water wheel driven by the water entering the apparatus.

FIG. 2.



The southern aspect of the Northwood Sanatorium.

A complete system for the protection of the buildings from fire has been installed and by means of call bells and telephones communication can be effected between the medical staff, matron, wards, and various administrative departments.

The style adopted in designing the sanatorium (Fig. 2) is a free treatment of Georgian, simple in character and well suited to the purposes of the building. By a happy selection of materials a good colour scheme has been obtained. As regards the general decorative effect the walls are faced with Luton grey bricks, with a proportion of red bricks indiscriminately introduced. The covered ways, too, are artistically built. When patients have to reside for some months in an institution of this kind their surroundings must naturally have an effect upon them. If an austere style is adopted a feeling of depression is likely to be produced but in designing this sanatorium Mr. Wheeler has adopted a style of decoration which can only have a beneficial influence on the inmates. Architecturally the winter gardens add much to the interest of the south front, while affording considerable shelter to the terrace. The terrace is paved with red tiles and bounded on the south side by a dwarf wall and piers having simple moulded stone caps. Flights of steps opposite the entrances lead down to the level of the grounds. The chapel is situated within easy distance from the main building. It is simple in its architectural treatment, Gothic in its lines, and is satisfactorily ventilated. The drainage of the whole building has been carried out according to the most approved principles of sanitation and is connected with the main system of the district.

One of the essential points in sanatorium treatment is that due opportunities for systematic exercise should be afforded to the patients. The grounds of the Northwood institution have been well laid out for the purpose. The walks for the male and female patients have been kept entirely distinct. This is not always easy to do, but experience has shown that it is by no means an unimportant detail. Another important matter is that suitable employment must be found for the patients, otherwise a few months' enforced idleness has a demoralising effect on them. We noticed that some of the patients were occupied in gardening and doubtless this is one of the best forms of work for a tuberculous individual to undertake. The grounds of a sanatorium constantly require attention and it is better that these duties should be done by the patients rather than that help should be procured from outside. The committee of the Mount Vernon Hospital may be congratulated on the possession of a sanatorium which fulfils all the requirements for the effectual treatment of pulmonary tuberculosis. It will also serve a second important duty—namely, to instruct the patients how to conduct their lives when they return to their occupations, both as regards themselves and in preventing the communication of the disease to others.

THE ARMY MEDICAL REPORT FOR 1903.

CONCLUDING NOTICE.[1]

AT the close of our first notice there remained a few points which had still to be touched upon. We have already called attention to the prevalence of enteric fever among British troops serving in India in connexion with the increased amount of susceptible material arriving in the command in the large drafts and reliefs coming from home and South Africa. Before dismissing this subject altogether it may perhaps be well to add that the special predisposition of the young soldier to contract enteric fever during his first year of service in India has been noted in every report of the Army Medical Department since 1872.

> The increase in the number of men of the most susceptible age will account for an increase in the actual number of admissions and the more the cases the greater the probability of further infection; this was brought to notice in the report for the year 1902 and is still further borne out by the reports for 1903. In 1901 there was a great diminution in the number of men of the susceptible age and a retention in this country of mature and seasoned soldiers and time-expired men; this was during war pressure and consequently the prevalence of enteric fever was much reduced.

We notice that there were only 12 admissions with two deaths from plague in 1903, against four admissions and one death in the previous year. Considering the terrible prevalence of that disease among the native Indian population this says much for the prompt judgment and care with which prophylactic measures were adopted and enforced in the case of the troops.

Malarial fevers formed, as usual in India, a main source of sickness and inefficiency in 1903. It is noteworthy that of recent years there has been no recurrence of any great cholera epidemic, about which we used to hear so much from time to time in the past, but the disease was nevertheless somewhat more prevalent and fatal in 1903 than in 1902.

Returning, however, to that section of the report which deals with the United Kingdom the reader will find at pages 30 and 31 some remarks, together with a table, showing the health statistics according to arms of the service; that is to say, the table gives the admissions, deaths, number of men invalided, and number constantly sick from each arm of the service, with the ratios per 1000 of strength. It will be seen that the Foot Guards do not occupy a favourable position in 1903 in respect of admission, invaliding, and constant inefficiency rates as compared with other arms of the service for they head the list. As regards the rate of mortality the Foot Guards, while showing the lowest death-rate in 1903, took the second highest place in this respect in the previous year—the regimental depôts being in the unenviable position of first. In the Household Cavalry, on the other hand, the different rates are relatively low and contrast very favourably with those of the Foot Guards.

Turning to the subject of recruiting for the army, the report for 1903 is an elaborate compilation containing as usual a number of statistical tables and details. The number of recruits inspected during the year was 69,553. Of these 22,382, or 321·80 per 1000, were rejected as unfit and 47,171, or 678·20 per 1000, passed fit for the service. 1022 of the latter were, however, subsequently discharged as unfit for service within three months of enlistment, thus making the total number of rejections equal to 23,404, or a ratio of 336·49 per 1000.

A comparison with the corresponding ratios of the previous year (1902) shows an increase of 14·61 per 1000 in rejections. The various causes of rejection are classified and set forth in tabular form at p. 43 of the report. Taken as a whole, they disclose a very unsatisfactory state of affairs, for they point to a growing deterioration in the general physique of that portion, at any rate, of the population from which our army is recruited. The subject is one of serious import and never more so than at the present time. Nor does it seem to us that any Government has made an earnest attempt to get at the root of the matter. What has still to be recognised generally is that we require an army which shall be expansible at need by the coöperation of all classes at home and in the colonies. Can it be said that the Government has any really adequate grip of the situation? The antiquated and lingering dread of so-called "militarism" can only be regarded as an anachronism nowadays and in present circumstances. Allowing for any additional causes for rejection which have been introduced of late years and such as did not formerly exist, and for any increased stringency on the part of medical examiners, can it be said that the War Office authorities have made the best use of the means at their disposal for making an entrance into the army more attractive to the recruit?

It is unfortunate that these army medical reports are belated publications, for it naturally tends to rob them of much present interest, but we suppose that for official reasons this is unavoidable. But we may say that, speaking generally, the report for 1903 is a more than usually good one.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia was held on June 23rd, Sir RICHARD DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

The following communications were received: 1. From the secretary of the Royal College of Surgeons of England, reporting certain proceedings of its Council on May 11th. 2. From the General Medical Council drawing the attention of the College to a list of rejections at recent competitions for commissions in the Navy, the Army, and the Indian Medical Services, indicating the licensing bodies from which the rejected candidates obtained their qualifications. 3. From the secretary of the Royal College of Physicians of Edinburgh denying that the College encourages the use of the title of "doctor" by its licentiates, not being graduates in medicine. 4. From the principal librarian of the National Library of Turin returning thanks for the books presented to the library by the College in January last. 5. From the Board of Education, forwarding papers, received through the Foreign Office, from the committee for organising a first International Congress on Radiology and Ionisation to be held at Liége on Sept. 12th to 14th next.

The TREASURER (Sir DYCE DUCKWORTH) exhibited to the College certain relics of Dr. Edward Jenner which had been presented to the College by Sir Samuel Wilks. The thanks of the College were ordered to be communicated to the donor.

A report was received from the College representative (Dr. Norman Moore) on the General Medical Council on the proceedings of the Council during its session in May last.

A report, dated June 5th, from the committee of management was received and adopted on the recognition of the Medical School at Cairo as a place of study for candidates for the diplomas of the two Royal Colleges.

A second report from the committee of management was received and adopted recommending some additions to the regulations for the public health diploma.

The REGISTRAR (Dr. E. LIVEING) moved that the following by-law be enacted for the first time, viz.:—

> That Leonard Rogers, M.D.Lond., elected to the Fellowship on April 27th, being resident in Calcutta, be admitted *in absentiâ*, any by-law to the contrary

---

[1] The first notice was published in THE LANCET of June 24th, 1905, p. 1740.

THE LANCET.

LONDON: SATURDAY, JULY 1, 1905.

Lunacy Acts Amendment Bill (London) (No. 2).

UNDER this heading a Bill has been ordered by the House of Commons to be printed (April 18th, 1905) the purport of which is "to authorise the London County Council to provide receiving houses for the reception of persons mentally affected or alleged to be of unsound mind, and to authorise the detention of such persons in such houses, and for other purposes connected therewith." The Bill was presented by Sir John Batty Tuke and supported by Mr. Burns and Mr. Benn. There has for some time been considerable agitation, in deference to the recognised objection of the relatives of persons suffering from recent mental impairment to place them under certificates or in an asylum, in favour of a change in the law. It has been desired to secure the detention under more liberal conditions as regards certification and restraint of such persons as are mentally afflicted but who may be reasonably expected to be suffering from disease of only a temporary character. The London County Council, noting the number of acute cases sent into its asylums and that many of these patients have to be discharged after a very short residence, and recognising that it is unfair and improper to brand such persons as "lunatics," has come to the conclusion that it should be empowered to erect reception houses to serve as filters through which mentally affected patients should pass, so that they may have the opportunity of demonstrating whether they are merely suffering from a temporary derangement, requiring only care and a short period before recovery, or whether the illness is more serious, demanding the usual process of certification and incarceration in one of the asylums. Hence the Bill now under consideration, which has been presented to the legislature by an eminent alienist and is backed by two prominent members of the Council. The experiment is an expensive one, entailing the erection of costly buildings and ambulance stations, accommodation for the treatment of out-patients, and provision for a large staff of officers. We conceive it to be our duty, in the interests of the public and of the patients, to criticise the proposed arrangements and to point out that material modifications are necessary to the success of the scheme, if, indeed, it is expedient to carry it out.

It will be granted that if a modification of the present lunacy law is necessary in the case of well-to-do patients it is right that a similar proposal should be made for pauper patients affected in a like manner, having regard, that is, to the view that if the present conditions are adverse to the recovery of the well-to-do patient they also act equally adversely to the pauper patient. We may point out that another Bill to amend the Lunacy Acts, dated April 18th, 1905, has been presented by the Attorney-General and supported by the Solicitor-General, the main feature of which is the "temporary care of incipient lunatics." This Bill provides that in certain circumstances a person suffering from probably curable mental disease may be placed for a period of six months under the care of a "person whose name and address are stated" upon the certificate of a medical practitioner. This Bill is almost certain to become law. What a difference in the two processes which have the same end in view! In the case of the private patient there is no mention of special provision of an institutional character or of the justice of the peace—nothing beyond the mere certificate of any medical man that in his opinion So-and-so is suffering from mental disease of a not confirmed character. These simple conditions are not possible in dealing with the poorer classes who cannot be placed in the costly homes accessible to the well-to-do. If they are to reap the advantages of the proposed modification of the law they must be provided with special places for treatment, not asylums but hospitals, inasmuch as the very essence of the new scheme is to do away with the opprobrious term "asylum" and all associations with the word. And here comes in the weakness of the new scheme as at present drafted in the Bill—to all intents and purposes the new "receiving house" is an asylum and unless it be conducted on very broad lines it will be esteemed as such. The term "reception house" is unfortunate; it savours too much of other "houses," the workhouse and the house of detention, and since, according to the drafted Bill, the institution is to be for "persons alleged to be lunatics" and is to be "conducted as nearly as possible in accordance with the law regulating county asylums," we have little difficulty in surmising that it will be held in public estimation to be something between an asylum and a prison. What is the difference? There are to be a "detention certificate," the interference of a "justice," the power of restriction of liberty and control by an organised staff, the "supervision of the Commissioners in Lunacy" and the mixture of all classes of "alleged lunacy" with "mental disease in its earlier stage or of the symptoms of incipient mental disease." All this sounds to us very like the present "asylum," even though Clause 18 of the Bill (p. 7)—a Bill, be it remembered, drawn up "to establish houses for persons alleged to be lunatics"—offers a salve to the conscience by stating that "a patient detained in a receiving house shall *not*, unless certified as such, be deemed a lunatic." Practically the very individuals whom it is desired to treat as merely sick persons will be housed with legally "certified lunatics" and will be under the bond of a detention order and the surveillance of the Commissioners in Lunacy. Is this realisation of an abstract idea worth the enormous expenditure entailed by the erection of new detention houses and ambulance stations in various areas or districts in the county? Will it be of any real advantage to the patient to tell him that he is not what he is practically made into? Regulations may abolish locks on doors, may dress attendants in ordinary clothes instead of uniform, may carefully allude to the patients as not insane or not "lunatic," but so long as the inmate of an institution is placed in the only two classes of detained persons in this country, lunatics and prisoners, he will be regarded as belonging to one class or the other. The contemplated provision for the treatment of out-patients is not bad in theory but inasmuch as persons can now get what they want in that way at the general hospitals it is doubtful if they will attend at the proposed "houses"; they will think that they run the risk of detention if their symptoms are unfavourably judged by the medical authorities of the institutions.

The additional cost of these proposed houses to the over-burdened ratepayer has to be taken into consideration. After "areas" have been secured in convenient places—and to be of any use they must be in London—the question of the style of buildings and the extent of them will have to be considered, and as the price will figure out at probably £200 a bed it will be seen that the proposition may easily run into hundreds of thousands of pounds, to say nothing of a weekly maintenance rate of something like 12*s.* per head. And what is the good to be achieved by this new expenditure? True, the present asylums will be less pressed, and it may be argued that as new accommodation has constantly to be provided it may as well take the proposed shape as any other. But most of the existing asylums have already accommodation of the very best kind for the treatment of acute cases and it seems ridiculous to devote this to the housing of the merely chronic insane, a result probably within the view of the new Bill, for it looks as if very few cases will be sent directly to the asylums—only when the patients have passed the test of the receiving house will they be apportioned as seems good to the authorities. No sooner will the "houses" be opened than they will be filled and the ratepayers will find themselves the supporters of many forms of nervous disorders which are better treated at the general hospitals. At the present time the workhouse actually does the work contemplated by this new Bill and in many instances does it very well. It would be worth while to obtain information from the central office of the asylums department of the London County Council on the following question—How many applications are received from the workhouses which are afterwards cancelled because the patients for whom application was made have recovered, or have been taken away by their friends? We know that the number is considerable and that beds which have been allotted in the asylums are frequently not wanted. If it is intended to pass all cases of insanity, incipient or pronounced, through the reception houses there will be no need of the present workhouse accommodation for these cases, but the substitution of one kind of officialism for another hardly justifies the abolition of machinery already in working order. The machinery may not be perfect but it is capable of improvement and of being made completely adequate for the purposes of this new Bill. The Local Government Board is surely as good a curator as the London County Council. Why cannot the Board be intrusted to see that the workhouse infirmaries are perfected for these purposes, purposes which they actually now do carry out, without burdening the rates with a new and costly experiment? It should be recognised that though the principle of temporary treatment before committing to an asylum should hold with regard to the poor as well as to the rich, there is no binding necessity that the methods to attain this end should be precisely similar, and therefore that it is no hardship for the poor person to be treated in the workhouse under revised conditions though the richer person may by his wealthier circumstances have the luxury of treatment in the house of a private individual. Let us look facts in the face. The County Council, we know, thinks that it is an objection for poor people to be termed "paupers" and to be treated in a "workhouse," and to obviate these fancied evils it proposes to saddle the ratepayers with elaborate buildings which are for all practical uses houses of restraint in which persons are to be treated at the charge of the rates, and no ostrich-like shutting of the eyes to facts will alter the real truth. If, however, the Bill does become law we hope that advantage will not be taken of its powers to begin buildings on different areas at the same time. Let one be erected in order to gain experience and to test the potentialities of the new ideas.

◆

Small-pox in Leicester during 1904.

ONE of the most interesting and as yet inexplicable phenomena in the history of epidemiology is the varying prevalence, fatality rate, and degree of infectivity of certain communicable diseases. Why is it that for years diseases such as plague, cholera, and influenza may either remain latent or confined to their endemic centres and then, bursting their bonds, spread over the world in a pandemic wave? Why is it, too, that at times small-pox is attended with a truly terrible fatality rate, while at others the disease, though prevalent, can hardly be detected in the bills of mortality? For several years past small-pox has evinced, not only in this country but also in the West Indies and elsewhere, such a remarkable mildness that, as at Cambridge, the true nature of the malady has been matter for speculation, and such mildness has manifested itself not only in well vaccinated but also in badly vaccinated communities. One of the best illustrations of this fact is to be found in the history of small-pox in Leicester during 1904 as set forth by Dr. C. KILLICK MILLARD in his last annual report. There were in Leicester during last year 321 cases of recognised small-pox and the table below gives certain facts both with regard to the vaccinated and unvaccinated :—

	Cases.	Deaths.	Fatality rate.
Vaccinated	127	1	—
Unvaccinated	192	3	—
Uncertain	2	—	—
	321	4	1·24

The death in the vaccinated group was that of a male, aged 46 years, of drunken habits, in whom the evidence of vaccination was open to doubt. But the point which is of greatest interest is the low fatality rate among the unvaccinated. It is clear, indeed, as we have already said, that small-pox may at times be so mild that inasmuch as there are but very few fatal cases the influence of vaccination is hardly detectable in the death returns. It has, however, to be pointed out that even in mild types of the disease, such as are here in question, the protective effects of vaccination are at once apparent if they are sought for in the proper channel. Although there were in the outbreak under discussion 125 cases under 15 years of age not one of them occurred among the vaccinated class, whereas the three deaths among the unvaccinated occurred in children under ten years of age. To this point Dr. MILLARD bears ample testimony when he says, referring to the figures for both 1903 and 1904, "there was not one single instance of the disease attacking a person who had been recently vaccinated before exposure to infection," but seeing that in 1904 no vaccinated person under 15 years of age was attacked a somewhat elastic use is perhaps made of the word "recent." The records with regard to the hospital staff are equally remarkable and Dr. MILLARD'S observations in this connexion will probably be freely quoted. He tells us that the majority of the staff employed in 1903 were also employed in 1904 and that of the 74 persons so employed every one, with the exception of three who had had small-pox before being engaged, had been recently vaccinated. After recounting the manner in which the staff were brought in contact with the patients and adding that during the two years nearly 700 cases of small-pox passed through the hospital, he is able to report that not a single member of the staff contracted "this most infectious disease." In seeking for an explanation of this immunity he refers to the suggestion which would certainly be made in Leicester that it was secured "by other means which were taken" and not by vaccination. To this he, replies that "as medical superintendent of the hospital and responsible for its management I ought to know what precautionary measures were taken, and I say emphatically that *beyond vaccination no steps whatever* were taken to protect the staff. I knew that with efficient and recent vaccination no other measures were necessary and that without it none would be of avail."

It must not, however, be concluded that Dr. MILLARD is what may be termed an enthusiast in the matter of vaccination. On the contrary, he thinks that in the recent epidemic the anomalous type of the vaccinated cases rendered them very difficult of detection, and to five "unrecognised" cases of this type he attributes the occurrence of no fewer than 40 other cases in the space of four weeks, and although he makes a confession of faith in writing "I believe absolutely in the protective power of vaccination" he thinks it possible (*a*) that the importance of universal vaccination, as also the terrors of small-pox, have been over-estimated; and (*b*) that the objections to vaccination and the efficacy of modern preventive measures have been under-estimated. We presume that this under-estimation argument is not intended to apply to Leicester where we are sure even Dr. MILLARD would admit that the virtues of the "Leicester method" and the terrors of vaccination have been proclaimed *ad nauseam*. It is, however, only fair to Dr. MILLARD to point out that with regard to the "Leicester method" he writes: "I will say at once that I consider it is too soon yet to arrive at a final conclusion as to its value" and he expresses the view that "Leicester's danger lies in the fact that the popular feeling against vaccination is so strong that if a breakdown of the present system did occur it is unlikely that the people would submit to universal vaccination until a very serious catastrophe had occurred." Leicester has, he thinks, succeeded in the past not *because* she has abandoned infantile vaccination but in *spite* of having done so and he regards it as "pitiable" that other communities should copy Leicester in the matter of abstention from vaccination but should fail to copy the other portions of her "method." Dr. MILLARD'S report will, we imagine, be read with very mixed feelings by the members of the Leicester borough council since he frankly tells the antivaccinationists that in trying to disprove the protective value of vaccination they are leading an utterly forlorn hope and he appears to us to suggest that they would do better to throw overboard this plank in their platform and, closing their ranks, to march forward under the "no compulsion" banner. We wish that he could use his influence with the people to adopt the method "made in Germany" rather than that of their own manufacture, and the fact that in Leicester during 1904 40 cases of small-pox are attributed to five "unrecognised" cases should in our view have led Dr. MILLARD to emphasise the need for systematic general revaccination. It is only by this means that the effect of anomalous cases can be guarded against, that business disturbances can be prevented and that the costly expenditure in small-pox hospitals can be obviated.

The Peterhead Hospital.

PROVOST LEASK of Peterhead is a gentleman who has the courage of his opinions. We publish elsewhere the observations which he is reported to have made on the occasion of laying the foundation stone of a hospital for infectious diseases in the burgh over which he presides, observations which appear to show a quite curious want of power to appreciate the real circumstances and necessities of the case. If local authorities in other Scottish ports resemble Provost LEASK, his denunciation of the Scottish Local Government Board may well excite lively feelings of gratitude for its existence and for its activity. His case is that whereas "a small cottage hospital with two or three beds has amply served the necessities of the burgh for the last 20 years or more and has been the only hospital in the place," the local authorities have been compelled by "a body of gentlemen in Edinburgh who had been formed by a grandmotherly government into a sort of moral policemen" to establish an isolation hospital which is to be of the villa type, built in four blocks and containing 16 beds. The worthy provost went on to inform his hearers that the aforesaid "moral policemen" required no knowledge of local needs or local circumstances and that the less they knew of them the better they would be prepared to carry out "cast metal rules and regulations" which they were "privileged to apply and enforce with something resembling the despotism of a Russian Tsar."

The circumstance that Peterhead never had any hospital at all until 20 years ago, and that since then its "small cottage hospital with two or three beds" has "amply served" the requirements of the locality is a statement which may go far to justify Provost LEASK'S praises of the salubrity of the town over which he presides, although it also suggests more than a possibility that the requirements in question may at least be partly supplied by the hospitals of Aberdeen. But the real crux of the question is in the fact that Peterhead is a port, with an extensive export and import trade, and that isolation hospitals at ports form essential portions of the defences of the country against foreign epidemics. According to the latest statistics which we have at hand the population of the burgh is about 12,000, and the shipping entering the harbour amounts annually to some 60,000 or 70,000 tons. This tonnage is more likely to increase than to diminish, because, although the port is no longer a centre of the seal and whale fishery, a new harbour of refuge has been constructed by convict labour, and any increased facilities for commerce are certain to be developed to the utmost by the energetic population of the place. As human nature is constituted it is not impossible that local laxity in the enforcement of port sanitary regulations, especially if rendered inevitable by the absence of the means necessary for carrying them into effect, might be a condition not wholly unattractive to skippers whose crews had been stricken by disease, and might tend to convert Peterhead into a sort of heel of ACHILLES in the general invulnerability of Scotland. The isolation hospital of a busy shipping port is not so much required for the dropping cases of infectious disease which may arise among the residents as for the protection of these residents and of the country generally against the diseases which may be imported from abroad. Energetic action was taken by the Local Government Board for England twelve years ago, in order to obtain the establishment of proper isolation hospitals at all the ports under its jurisdiction which were not already provided with them; and, if Peterhead has been allowed to be content with the possession of "two or three beds" until now, it would seem to us that the action of the Scottish Board should be condemned for its tardiness rather than for its despotism.

History is only too full of evidence, moreover, that the sort of official optimism which seems to prevail at Peterhead is not always a trustworthy indication of the nature of the facts on which it rests. Where there is but an inadequate provision for dealing with certain classes of evils there is likely to arise a general impression that they must remain undealt with, and an acquiescence in the consequences of neglect as if these ought to be regarded as unavoidable. Where little or nothing is done for the mitigation of disease its presence comes to be regarded as part of the order of nature; and where persons in authority have neither the means nor the inclination to act effectively, effective action soon ceases to be either expected of, or demanded from, them. To say that a cottage hospital with two or three beds has been amply sufficient for the needs of an industrial population of 12,000, busily engaged as fishermen, sailors, quarrymen, stone-cutters, ship-builders, and so forth, and liable not only to all the ordinary forms of disease but also to their due proportion of accidents, seems to us to be an incredible proposition, the maintenance of which can only be explained on the ground of ignorance of the amount and kind of provision which like conditions are found to justify and to demand elsewhere. We fully agree with the proposition that the requirements of a central authority should be governed by sufficient local knowledge, but we cannot admit that they should be governed by possibly uninstructed local opinion. Provost LEASK condemns the Local Government Board for "seeming to believe that local men knew nothing about the requirements of their localities or could not be trusted to do their proper duties." It must be conceded, on the one hand, that such a belief may be carried too far but it may safely be maintained, on the other, that it often rests upon a very considerable body of evidence. The recent epidemic of typhoid fever at Lincoln has admirably illustrated the capacity for inaction which may be exhibited by local men in the face of conditions absolutely certain to produce disaster, and the case of Lincoln has been exceptional only as regards the magnitude of the outbreak which has been permitted. Every recurring annual report of the medical officer of the Local Government Board contains accounts of epidemics produced by causes to the existence and character of which the attention of the local authorities had been repeatedly directed, but which had none the less been suffered to remain unchanged; and it is well known to all sanitary administrators that the owner of a dangerous nuisance is almost invariably solicitous to obtain a seat on the board by which this nuisance ought to be suppressed. On such a board, as a rule, his sole function will be the protection of his property against the demands of the inspector or of the medical officer of health. Provost LEASK is, no doubt, plausible but in the face of facts which are well known to all of us, and some of which, indeed, are disclosed by his very arguments, we are unable to say that he is convincing. His criticism will be useful in so far as it may render Local Government Boards careful in their inquiries but it can hardly be said to convict the Board for Scotland of hasty or inconsiderate action. Before many years have passed away the inhabitants of Peterhead will probably have ample cause to congratulate themselves on the consequences of the official pressure of which their provost now complains and to regard their new hospital with a satisfaction based upon experience of its utility.

Annotations.

"Ne quid nimis."

THE DEFICIENCIES OF BRITISH INNS.

THE holiday season is approaching and we constantly hear recriminations addressed to those who choose to spend their holidays abroad instead of in their own country. It is quite true that these islands have objects of interest quite equal to those possessed by foreign countries, but in our opinion the traveller who makes holiday in Great Britain by means of a driving, cycling, or motoring tour is not catered for in anything like the satisfactory way in which he is in even the smaller towns or villages of provincial France. We have received a letter from a correspondent who has recently returned from a tour in the county of Kent which thoroughly bears out our contention. He says:—

> I have recentl [illegible] bridge Wells and send [illegible] to your readers and, I [illegible] hance these lines shou [illegible] hich is famous for one c [illegible] sts an "institute" erec [illegible] light refreshments. [illegible] uash. "We've no lemons," was the answer. I inquired if no lemons could be got in the village, there being a grocer's shop some 20 yards away. "No," said the man in charge, "there's no such thing to be got in ——." So I had to go myself, buy two lemons, and come back, when

I was grudgingly provided with some flat soda-water out of a syphon and some sugar. I rode on *some miles farther and stopped at* ——, where there is to outward seeming a charming inn. There are flowers in the windows, trees with benches outside; inside, a grand piano, two ancient amphoræ in the hall, a photograph of the Duomo at *Florence, a plan of the drains,* a smiling manageress in black silk, and a courteous manager in light grey dittoes and a red tie. I thought this looked promising and asked if I could have some lunch. "No," said the lady in black, "we've nothing in the house. If you like to wait half an hour we can give you a chop or a steak." "Nothing cold," I said. "No, there's no demand for it." Eventually the gentleman in grey said he thought that there was cold tinned tongue. There was, and I had it. There were no lemons, of course, but I had brought one with me. A few days later I rode to another place distinguished for having a church with some excellent modern windows by a distinguished artist, *some* interesting old houses, and an inn the building of which dates back to about 1450 in places. Here an almost exactly similar scene was repeated. Again I was offered a chop or a steak; again I had to put up with a tinned tongue (American); again, warned by experience, I had provided my own lemon. A friend to whom I recounted my experiences told me that just the same happened to him at the principal inn of the place where I had my encounter with the institute keeper. He had taken two friends from America to see the historic house and offered them lunch at the inn. The only thing in the house was a very poor quality indifferently cured ham from Chicago. He was also charged 6*d.* for putting his bicycle in a shed. Is it any wonder, Sirs, that persons who can have but a short holiday prefer to go to Normandy or Brittany where one is always sure, even in a *little village,* of civility, a good omelette, fresh vegetables, and generally a little soup?

We agree with our correspondent. The British innkeeper in the *Home* Counties, at any rate, does not seem to care in the very least about the comfort of his guests. His only object is to sell intoxicating drinks. In many instances this is not altogether his fault for he is the victim of the tied-house system. But the difference between the British inn and the foreign one is very striking and we are sure that if some innkeeper in any one of the interesting old towns to be met with within 40 miles of London would lay himself out to provide travellers with a *simple,* cleanly meal of cold beef, fresh salad, lemons, strawberries, and other fruit when in season, and would not charge 6*d.* for standing a bicycle *up against* a wall, he would reap his reward.

THE METROPOLITAN WATER-SUPPLY.

A LETTER appeared in the *Times* of June 23rd from Mr. R. Brudenell Carter, F.R.C.S., in which he described a sudden cessation of the domestic water-supply of dwelling houses in Clapham, Balham, and Tooting, although the service for watering the roads underwent *no interruption* and although no warning of any probable scarcity had been given to the consumers. The only explanation obtainable by Mr. Carter from "irresponsible clerks" at the district office of the Water Board was that a shortage of supply had been occasioned by the difficulty of filtering water which had been rendered unusually turbid by the recent heavy rains; and that this shortage, although it interfered with the domestic service to cisterns on the upper floors of houses, did not interfere with the service to standpipes at lower levels and thus permitted a sufficient supply to be given to the watering-carts. The excuse was a *foolish* one, because the height to which the water service will reach is almost entirely governed by the quantities which are withdrawn at lower levels, and hence *if the street* service had been temporarily arrested that to the houses might unquestionably have been continued. From inquiries which we have made we learn that no water entered the houses for more than 24 hours, and we regret to add that there is no evidence on the part of the Water Board or of its servants of any adequate appreciation of the character of the failure *of duty of* which they have been guilty or of the consequences possibly attendant upon it. Sir John Simon once called attention to the very imperfect manner in which the public was protected "against certain extreme dangers which the malfeasance of a water company, supplying perhaps half a million customers, may suddenly bring upon great masses of population. Its colossal power of life and death is something for which until recently there has been no precedent in the history of the world; and such a power, in whatever hands it is vested, ought most sedulously to be guarded against abuse." So little has this been done that the safeguards which existed in the time of the companies have practically been entirely withdrawn by the *establishment of* the Board. We are advised that the previous Acts relating to the companies are not expressly incorporated in the Act constituting the Board. It is only provided that the Board shall be subject to all the duties, obligations, and liabilities of the companies in like manner as if it were the companies, and these words do not expressly provide that the penalties which were recoverable from the companies in police-courts for breach of obligations may also be imposed upon the Board. In these circumstances it is doubtful whether a police magistrate would inflict a penalty and if he did the case would unquestionably be taken to the High Court at the cost of the ratepayers, upon whom, in any case, and not upon the delinquents, the penalties would fall. Mr. Carter saw many persons engaged in fetching temporary water-supplies from a pond on Clapham-common in which tramps are in the habit of washing themselves and their clothing, and he referred to the dangers of typhoid fever which the use of such supplies might entail. Apart from this, it is obvious that the complete absence of water from hundreds or thousands of *houses might easily* be productive of fatal consequences in many ways, and if the Water Board continued to fail in the discharge of its duty the verdicts of coroners' juries would be likely before long to direct the attention of Parliament to the necessity of increased provision for the public *safety*. It is obviously the duty of the Board to provide *filtering* areas sufficient for times of unusual turbidity of the supply, and to meet any *unavoidable shortage* (*of the* occurrence of which there is always ample foreknowledge at *headquarters*) by giving such warnings as may be productive of *economy in the* use of water, and by sending round water-carts or by *establishing temporary stand-pipes* in localities where the domestic supply is suspended.

PRECIPITATE LABOUR.

HAPPILY it does not often occur that cases of precipitate labour entail the death of both the mother and child as in the very interesting case recorded by Mr. H. E. Rayner and Dr. W. L. Stuart in THE LANCET of June 17th. Cases of this kind are not infrequent and in quite a number of instances delivery *has occurred* whilst the mother was in the closet. In a case published by Colton a woman aged 25 years felt a desire to urinate and whilst *seated on the closet gave birth to* a child. She had felt no pains and twelve days later is said to have ridden twenty miles to the funeral of her baby. Leonhard describes the *case of* a woman, aged 37 years, who had had six living children and who was pregnant for the tenth time: she had taken an aperient and on attempting to *rise* after the bowels had been opened found herself attached to the closet by the cord. The child lived but the mother died half an hour after returning to bed. *There is* a curious story related by Gould in his book on the "Curiosities of Medicine" of a woman who is said to have been delivered of a child in the lavatory of a railway train, the child afterwards being found alive on the track! In *another* case quoted by the same author a woman, aged 40 years, who had borne two children, was *delivered* so suddenly whilst in a bath that the child *was in* danger of drowning. The question as to whether a healthy woman can be delivered unconsciously is one of much medico-legal *interest. It is difficult* to understand how a woman can mistake the onset of labour for a desire to pass urine or to defæcate. It is interesting to note, however, that patients not uncommonly say that the discomfort experienced by them when the bladder is over-distended is not unlike that felt at the onset of the monthly periods. It is difficult to understand the possibility of an error in these matters, but as such an excuse is often put forward in cases where women are accused of the wilful concealment of birth it is well if possible to give them the benefit of the doubt although the plea is generally not a true one. At the Barking outfall of the London sewers at one time they received an average of five fœtuses a year and it is unlikely that many of them got into the sewers without the knowledge of the mothers. The occurrence of a case of precipitate labour no doubt depends upon the combination of a number of different factors. Winckel as the result of his investigation of some 250 cases of this kind concludes that the most important and constant of these factors are: excessively powerful pains, multiparity, such general affections of the mother as bronchitis and epilepsy, small size and macerated condition of the fœtus, and abnormal shortness of the cord. The most important of all, however, he considers to be the position of the patient at the time when delivery occurs, and as an explanation of the excessive force of the pains he suggests an abnormal development of the muscle of the upper uterine segment over that of the lower segment. He further points out that heredity plays some part, even according to Cazeaux as far as the third and fourth generation, while the condition may recur in the same patient in successive pregnancies. It is difficult to believe, as do the authors of the case recorded in our columns, that the premature separation of the placenta and intra-uterine hæmorrhage could have been the exciting causes of such extremely powerful uterine contractions. This complication of labour tends in the majority of cases to produce inertia of the uterine muscle rather than excessive action. It is uncommon, too, to find a rupture of the uterus; the more frequent complications are acute prolapse or inversion of the uterus and retention of the placenta.

A PRACTICAL INVESTIGATION OF THE EFFECT OF PRESERVATIVES UPON DIGESTION AND HEALTH.

THE remarkable experiments undertaken at the instance of the United States Department of Agriculture by Dr. H. W. Wiley, chief of the Bureau of Chemistry, with the view of determining the effect of certain preservatives upon digestion and health, have been concluded so far as boric acid and borax are concerned. A very interesting and complete account of the experiments, which were conducted on human subjects, has been issued. The report undoubtedly contains the most valuable contribution that has ever been made on this subject. The work has been conducted with admirable care and with a splendid regard to detail. 12 persons were selected for the purpose who were kept under constant supervision, including medical examination directed to the blood, the temperature and pulse, and the body weight. The preservatives were administered in foods which were analysed as regards their contents of water, fat, nitrogen, phosphoric acid, and heat-producing equivalent. The urine and the fæces were analysed. It may be imagined what a great number of analyses were thus involved and also what special difficulties there were connected with the work. While the results showed no startling record of symptoms there was distinct evidence of impairment of normal health in many cases. When boric acid or its equivalent in borax is taken with the food in small quantities not exceeding seven and a half grains a day no notable effects are immediately produced. Long-continued exhibitions of small doses or large doses extending over a shorter period show in many instances a manifest tendency to diminish the appetite and to produce a feeling of fulness and uneasiness in the stomach which in some cases result in nausea, with a very general tendency to produce a sense of fulness in the head often manifested as a dull and persistent headache. In addition to the uneasiness produced in the region of the stomach there appeared in some instances sharp and well-located pains, which, however, were not persistent. These sensations disappeared as a rule when the preservative was withdrawn. The administration of boric acid in quantities of from 60 to 70 grains per diem continued for some time resulted in most cases in loss of appetite and inability to perform work of any kind. In many cases the person became ill and unfit for duty. It would seem, therefore, that 60 grains per day is the limit of exhibition beyond which the normal man may not go. Most of those under observation were able to take 45 grains a day for a somewhat protracted period and still to perform their duties. They, however, felt injurious effects and it would seem certain that the normal man could not long continue to receive this quantity per diem with impunity and in some instances even seven grains per diem appeared to have a disturbing effect upon the normal health. The conclusion seems to be warranted, therefore, that both boric acid and borax when continually administered in small doses for a long period or when given in large quantities for a short period create disturbances of appetite, of digestion, and of health. These results, it seems to us, must gain acceptance considering the eminently practical way in which they were obtained. We look forward with very great interest to the indications which further experiments may give with other preservatives. In the meantime we congratulate Dr. Wiley on the patient, painstaking, and practical way in which he has approached the question and a word of praise is due to those men who voluntarily submitted themselves to the experiments.

LIQUOZONE IN THE CORONER'S COURT.

ON June 26th Dr. W. Wynn Westcott concluded his inquiry into the deaths of Constance Adelaide Sheppard and Dorothy May Sheppard who were alleged to have died from the effects of a patent medicine called liquozone. The proceedings at the opening of the inquiry were summarised in THE LANCET of June 10th, p. 1594. At the adjourned inquiry Sir Thomas Stevenson gave the results of his analysis of liquozone. The principal ingredients were: sulphur dioxide, 0·269 per cent.; and sulphuric acid, 0·848 per cent. The preparation was practically a solution in water of sulphur dioxide which had partly oxidised into sulphuric acid. Taken internally it would act as an irritant and might cause vomiting in a child. Mr. A. J. Pepper said that in his opinion the symptoms were due to food poisoning, possibly watercress, and Dr. A. P. Luff also said that food poisoning was to blame. He did not think that it was possible for liquozone to have caused the deaths. The jury returned the following verdict:—

> Both the children died from exhaustion, after vomiting and diarrhœa, set up by taking liquozone. They further wish to add their deep [illegible] with the parents in the loss of their children. They further [illegible] should be made to the proper autho[illegible] investigation should be made as to the nature of these patent medicines before they are placed on the market.

In the course of the case Mr. Andrews, on behalf of the children's parents, asked Sir Thomas Stevenson: "Should I be exaggerating if I said that the pamphlet was nothing but lies?" To which Sir Thomas Stevenson replied: "Not greatly. It has no foundation in fact." We desire again to insist, as we have done for many years past, that some control should be exercised over patent medicines and the lying statements by which they are puffed in magazines and, we regret to add, even in the better class daily journals. In the advertisement columns of most, if not of all, the popular sixpenny monthly magazines there will be found every kind of quack medicine and so-called medical appliance set out in the most glowing terms. In the June number of one magazine now before us there are over 40 such advertisements. The proprietors of these magazines pocket from £30 to £50 per page of dirty money for these announcements, so that it is obvious that the owners of the quack preparations must make enormous profits to be able to pay such sums. The Government connives at the sale and at the deception by insisting on the use of a 1½d. stamp. Either such quackery should be prohibited or the amount of the stamp should be raised to some prohibitive sum, or still better, any quack trader should be compelled to pay an annual licence to cost, say, £200 per annum. The liquozone quacks apparently keep a qualified medical adviser. Dr. J. R. Wallace It would be in accordance with the traditions of the profession to which he belongs if he severed his connexion with the company.

SMOKE ON THE RIVER THAMES.

WE said last week that the London County Council has done many things, for some of which it has been heartily praised and for others equally heartily condemned. In the former category we placed the recent inauguration of an efficient steamboat service on the Thames, a step which so far has met with considerable success, and we are quite confident that the London County Council would be the last body in the world which would knowingly detract from this success by committing a hygienic blunder. The London County Council is our health authority and amongst its duties in this connexion is the suppression of the smoke nuisance and its energies, backed by the vigilance of the Coal Smoke Abatement Society, have undoubtedly gained for Londoners a purer and a cleaner air. But if the new Thames steamers cannot be improved as regards their fires and stoking arrangements the river bids fair to flow under a dense and offensive pall of smoke, the beauty of the Embankment will be sadly marred, and the pleasure of a journey by water will be utterly destroyed. We are sure that on this matter being represented to the Council it will take steps to set its own house, as it were, in order, otherwise its praiseworthy crusade against manufacturers, the proprietors of hotels and restaurants, and others who commit a smoke nuisance will be nullified by its own neglect in the same matter elsewhere. Perhaps it is that the funnels of the new steamers are shorter than those of the old steamers but the London County Council steamers should be exemplary in this matter and our health authorities will do well to show their sincerity of purpose by demonstrating to others that the furnaces of river steamers need not be producers of smoke and vitiators of the otherwise fresh and pure river air.

PATHOLOGY AT OXFORD.

ON June 20th a deputation representing the graduates in medicine of the University, consisting of Sir William S. Church, Dr. S. J. Sharkey, Dr. G. I. Schorstein, Dr. W. Collier, and Mr. Whitley, presented an address to the Vice-Chancellor in Convocation. The purport of the address was to lay before the University a statement of the steps already taken to further pathological study in the University. The appeal for support, which had so far been limited to members of the profession, had resulted in the raising of a sum of £500 which was allocated to the ultimate endowment of the chair of pathology. It was now intended to appeal to the general public. Sir William Church concluded by asking the Vice-Chancellor to receive the address and an album containing 200 signatures. The Vice-Chancellor, in receiving the address, said that he was pleased that the importance of the chair should be thus emphasised. We are glad to see that the medical graduates of Oxford are doing what they can to place the chair of pathology upon a sound financial footing. But they are comparatively few in number and so we trust that other Oxford men and even members of the general public will contribute. If a sum of £10,000 could be raised which would provide the chair with an endowment of £300 per annum the University chest might make a larger grant than it at present feels justified in doing.

TOXIC SYMPTOMS AFTER OPERATIONS ON HYDATID CYSTS.

THE production of toxic symptoms by operations on hydatid cysts does not seem to have received much notice in English works. Thus the Australian writers, Dr. J. C. Verco and Dr. E. C. Stirling, in Allbutt's "System of Medicine," refer only to an urticarial rash. In the *Archives Générales de Médecine* of May 23rd Dr. Fuster and Dr. Godlewski have published the following case of "intoxication hydatique suraigue tardive." A man, aged 26 years, was admitted into hospital on Feb. 16th, 1905, for a tumour of the liver. He had been a soldier and had served in Africa, where he suffered from malarial fever. In August, 1904, he felt pain in the hepatic region and readily became fatigued. For the previous two months he had noticed a small tumour in the right hypochondrium. Examination showed an ovoid tumour which projected below the end of the seventh rib. The tumour was hard and gave the sensation of a cyst. There were slight hypogastric pain, a continual feeling of hunger, boulimia, constipation, and impeded respiration. On Feb. 22nd an incision was made over the tumour, a trocar was inserted, and a jet of limpid liquid escaped which contained a hydatid vesicle. A tumblerful of fluid flowed out and a solution of formol, 1 in 100, was injected into the cavity. The visceral peritoneum was stitched to the parietal and the sac was opened and 30 hydatid vesicles were extracted from it. The lining membrane of the sac was removed by curetting. A large drainage-tube was inserted and the wound was closed. The patient progressed until the morning of the 27th, when he could not sleep and complained of *pruritus* in the abdomen and limbs. No trace of urticaria could be found. The wound was in good condition and there was not a drop of pus. Clear liquid containing two flattened daughter vesicles was issuing from the tube. At noon the *pruritus* increased and at 3 P.M. the respiration became jerky. The patient perspired profusely and he sat in bed with his head hanging forward and could not raise it. The jaws were closed as if from trismus but could be opened easily. Kernig's sign was present. At midnight the head was maintained in the same position by slight contracture. The perspiration was diminished and there were jerky and convulsive movements of the limbs. There was a good pulse of 100 and the temperature was normal. At 9 A.M. on the following day the symptoms persisted, the intelligence was preserved, the respiration was of diaphragmatic type and jerky, and there was hiccough. There were asphyxial crises, cyanosed lips, local asphyxia of the extremities, and cold sweats. Convulsive movements took place. There were trismus, contracture of the neck, and involuntary grimacing. The patient replied to questions but no longer saw anything and the corneæ lost their lustre. The crises occurred more frequently, the respirations became more convulsive, the pulse became slower, and death occurred at 2 P.M. The necropsy showed a hydatid cyst of the size of the fœtal head growing from the right lobe of the liver and intimately adherent to the duodenum, the pancreas, and the posterior surface of the pylorus. It contained no vesicles and there was not a trace of pus. The wall was very vascular. The other abdominal organs were normal except that the spleen was large. The meninges and brain were congested and the latter was œdematous. It is noteworthy that symptoms did not appear until five days after the operation. Several cases have been recorded in which death occurred immediately after operation on a hydatid cyst, but such a late appearance of symptoms is rare. However, cases have been recorded in which symptoms appeared on the third and on the fifth days. Older writers (Cadet de Gassicourt and Frérichs) thought that such symptoms were due to a subacute inflammatory or septic process. But in this case there was no trace of peritonitis and there was no pyrexia. The most rational hypothesis is that the symptoms are a toxic effect of the hydatid fluid. Mr. Thomas Bryant has recorded a case in which some seconds after puncture of a hydatid cyst vomiting, syncope, and epileptiform convulsions occurred.[1] Chazoulière has reported the case of a man, aged 38 years, who had a hydatid cyst for 20 years. Four days before admission into hospital he was attacked with hiccough, fever, rapid respiration, and convulsions of the upper limbs. On admission the temperature was 104·9° F. On the following day there were coma and contracture of muscles and death occurred during an epileptiform fit. The necropsy showed diaphragmatic peritonitis and hydatid fluid in the peritoneal cavity. Chauffard has described the case of a vigorous man, aged 35 years, who had a hydatid cyst of the liver. After an exploratory puncture there followed malaise, anguish, and agitation. The patient suddenly scratched the neck, internal surfaces of the thighs, and lower abdomen. Two minutes later there was involuntary grimacing, with tonic contraction of the limbs, spasms of the face, cyanosis, and foaming at the mouth. After an interval of a minute a second attack of convulsions occurred and was followed by asphyxia and death 25 minutes after the puncture. The liquid of hydatid cysts seems to contain toxins which some have described as ptomaines, others as toxalbumins. The experimental injection of the liquid into the peritoneal cavity of animals has given variable results. Sometimes no effect was produced. In other cases such phenomena as fever, convulsive movements more or less generalised, and slow and difficult respiration followed. Intravenous injection causes more acute symptoms. These facts agree with the clinical observations that the symptoms of hydatid intoxication are variable. Pruritus, accompanied or not by urticaria, and erythema have been observed. Gastro-intestinal symptoms, such as nausea, vomiting, or diarrhœa, may occur. The most frequent results are collapse and syncope accompanied by cold sweats and coldness of the extremities. Often the pulse is strong and slow. Sometimes there is also acute dyspnœa ; there may be crises of asphyxia with slow respiration, which may be suspended, and cyanosis of the face and extremities, or there may be distressing hiccough. The crisis lasts two or three minutes. Death may occur from asphyxia or syncope. Absorption of the hydatid fluid seems to take place either through the peritoneum or through the wound. No method of operating furnishes a safeguard against such accidents which, however, are rare.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: ELECTION OF MEMBERS OF COUNCIL.

A somewhat unusual event has occurred in connexion with the approaching election at the Royal College of Surgeons of England. Mr. W. Bruce Clarke was one of the candidates; he had been nominated and his name had been placed on the voting papers, but he has now withdrawn. The reason for this has been given in a circular letter which he has addressed to the Fellows. Mr. Bruce Clarke states that when he became a candidate for the Council he was not aware that Mr. Harrison Cripps, who is his senior colleague at St. Bartholomew's Hospital, had decided to stand; but when he found that Mr. Cripps had been nominated he decided to withdraw. Under the regulations of the College Mr. Bruce Clarke's name will still have to come before the electors, as a candidate who has been nominated cannot withdraw his name, but, of course, Mr. Bruce Clarke's intimation that he does not wish to stand will have almost the same effect—the electors will not give him any votes. As the case now stands there will be only one unsuccessful candidate and this is certainly a condition of things which has never existed before at the Royal College of Surgeons. It is necessary that six Fellows should be present before the counting of the votes can begin and we would therefore suggest that any Fellows who can spare the few minutes needed should attend at the College to assist in the election. The time of the commencement of the election is 2 P.M. on Thursday, July 6th.

THE ORDER OF ST. JOHN OF JERUSALEM IN ENGLAND.

On June 22nd the celebration of the annual festival of the Order of St. John of Jerusalem in England was inaugurated by a sermon preached in St. John's parish church, Clerkenwell, London, by Archdeacon Sinclair. Referring to the work of the British Ophthalmic Hospital at Jerusalem, the Archdeacon of London said that the hospital contained 42 beds and that 560 in-patients were admitted in four months. The new out-patient cases numbered 6945. The operations performed were 1710, 898 of which were serious enough for the administration of anæsthetics Such work was better than all the conquests of the most heroic Grand Masters of ancient days. The ambulance branch of the Order was constantly performing public service and the Order was diffusing the spirit of health and healing among the community. Subsequently the members of the Order paid a visit to the crypt and adjoining chapel erected by the Knights Hospitallers *circa* A.D. 1170. The altar of the chapel has recently been provided with a hanging of old needlework presented by Lady Galway and believed to have adorned originally the chapel of St. John in the cathedral of Florence. Later, the annual general assembly was held in the St. John's Gate, Clerkenwell, under the presidency of Lord Egerton of Tatton, Chancellor of the Order, and on the following morning Holy Communion was celebrated in St. John's parish church.

DR. ARMAND BERNARD AND THE LIVERPOOL ROYAL INFIRMARY.

Much regret was manifested in professional circles in Liverpool when it became known recently that Dr. Armand Bernard, surgeon to the lock department of the Liverpool Royal Infirmary, and for some time the senior member of the staff of the hospital, was about to resign in consequence of his having completed his term of office as defined by the laws. It was felt that Dr. Bernard deserved some special consideration from the fact that at the time of the rebuilding of the infirmary he relinquished his wards which were utilised for medical cases during the four years from the closure of the old infirmary in 1887 to the opening of the new infirmary in 1891. As the lock wards were not rebuilt Dr. Bernard received no compensation for disturbance in the shape of improved accommodation, and the four years were, therefore, a dead loss to him. The committee of the Royal Infirmary has therefore decided that Dr. Bernard shall continue in office for two years longer. It should be pointed out, as justifying this resolution, that there is no assistant surgeon to the lock department, so that it does not keep back the promotion of any junior member of the staff and also that Dr. Bernard is clinical lecturer on venereal diseases in the University of Liverpool and the only systematic clinical teacher in that subject in the city. His Saturday morning demonstrations constitute an important part of the clinical teaching of the infirmary and are highly appreciated by the students and it is a matter for congratulation that they are to be continued.

---

[1] Transactions of the Clinical Society, 1877-78, p. 230.

"CHEMIST-OPTICIANS."

A RECENT number of our esteemed contemporary the *Pharmaceutical Journal* contains evidence that the curious hybrid designation above printed is shortly to come into use among dispensing chemists and that the action of spectacle-sellers in setting themselves up as practitioners in ophthalmology is bringing into the field a body of rivals who intend to dispute with them the profits of the new calling. "A Chemist-Optician Candidate" has been communicating to the *Pharmaceutical Journal* the particulars of an examination to which he has been subjected by the Spectacle Makers' Company and he relates his success in diagnosing and in prescribing for a case of compound myopic astigmatism and a case of "4 D. of esophoria in each eye." It seems unkind on the part of the spectacle makers thus to raise up rivals to the members of their own fraternity, and it is difficult to say at what point the influence of their proceedings will be stayed. Obviously, no "counter prescribing" will for the future be complete unless it takes due account of "eye-strain"; and before long we may have "*modiste*-opticians" who will undertake to supply fashionable ladies with glasses not only adapted to the requirements of their eyes but also so tinted and so constructed as to be in harmony with their successive variations of costume.

"RETURN" CASES OF SCARLET FEVER.

THE occurrence of so-called "return" cases of scarlet fever—that is, fresh cases apparently due to infection from individuals discharged from isolation hospitals as cured and non-infective—demands a careful consideration of the duration of the infective stage of the disease and the conditions which tend to prolong it. That such cases occur there seems to be no doubt, and Dr. Egerton H. Williams in his annual report of the infectious disease hospitals of the city of Sheffield for the year 1904 gives some interesting statistics. In a total of 1981 cases discharged from the hospitals after scarlet fever 70 were associated with the reappearance of that disease in the houses to which they returned or its development among persons coming in contact with them. On investigation of these 70 cases, however, it was ascertained that in a certain number other sources of infection could be found, so that Dr. Williams was able to eliminate 24 of them. Of the remaining 46, 19 were regarded as "improbable return" cases, leaving 27 "possible" cases—that is, cases in which no other source of infection could be traced and which were therefore probably true "return" cases. The importance of this matter is emphasised by a recent legal action in the Court of *Nisi Prius* before Mr. Justice Walton which is noticed in the issue of the *Times* of June 13th among notable law cases. The son of the plaintiff in this action when suffering from scarlet fever was removed to the hospital for infectious diseases provided by the Liverpool corporation. On his return home from the hospital he is stated to have spread the disease among his brothers and sisters. The jury found that there was a want of reasonable skill and care on the part of the medical practitioner appointed by the corporation in discharging the patient, and it was contended that the corporation was answerable for his acts. The judge, however, ruled otherwise, stating that the practitioner, though a servant of the corporation for some purposes, was not such for others; in discharging patients he acted merely as the adviser of the corporation. It is now very generally admitted that the discharges from the nose, throat, and ears of patients convalescing from scarlet fever are more infective than the desquamating cuticle except perhaps that first shed, while the secondary desquamation which occurs in some cases is probably not infectious at all. In Dr. Williams's interesting report previously referred to, it was found on investigation of the 70 individuals suspected of causing "return" cases that 13 had discharging ears, 14 a discharge from the nose, and five a sore mouth or nose, the remainder showing no abnormal conditions. At the time of discharge from the hospital all were noted as being perfectly healthy with the exception of the 13 ear cases. In the Sheffield fever hospitals cases with discharging nose or ears are isolated and if the discharge does not clear up while in hospital in ear cases arrangements are made with the parents of patients prior to discharge about their subsequent treatment. During the year 1904 303 cases were thus isolated, 112 going out cured. Of the remaining 191 only the 13 cases just referred to were suspected of producing "return" cases and on investigation of these seven were definitely proved not to have done so. These figures show the importance and the relative frequency of "return" cases; in other series of cases the frequency has been found to be from 1 to 1·86 per cent. They illustrate also the difficulties in determining when the period of isolation of cases of scarlet fever may be safely terminated not only in institutions but also in private practice. The Medical Officers of Schools Association advises that isolation should be maintained for "not less than six weeks from the date of the appearance of the rash provided convalescence is completed and desquamation has ceased, and there is no sore throat, discharge from ear, suppurating glands, or eczematous patches." Dr. Williams's figures and the experience of others show, however, that in spite of careful examination of cases before discharge "return" cases may occur even after prolonged isolation, the average stay in hospital of his 70 cases being 54·3 days. Unfortunately at present there is no bacteriological or other test available for determining whether cases are infective or not and no infallible means of disinfection are known—facts which make it difficult to endorse the views of the jury in the case mentioned above.

CERTIFICATES OF PROFICIENCY IN VACCINATION.

THE provisions of the Vaccination Order of 1898 required that any medical practitioner before he could enter into a contract with a board of guardians for the performance of public vaccination should produce a certificate of proficiency in vaccination. If he had not obtained such a certificate as a condition of obtaining his degree, diploma, or licence, he had to obtain one from some person duly authorised by the Local Government Board, and this could only be done after the applicant had been duly instructed and examined in the practice of vaccination by such duly authorised person. The Local Government Board has now issued an Order amending that of 1898 and in a circular accompanying that Order the Board sets forth the reasons which have induced it to issue the amending Order as follows:—

> It has been represented to the Board, however, that under this provision a person who took a diploma or degree from an examining body at a date wher [illegible] not require as a condition of such diploma [illegible] of the prescribed certificate of [illegible] the Order of 1898 to devote a [illegible] instruction in vaccination, although, as [illegible] may be fully conversant with the practice of vaccination and competent to perform the work of a public vaccinator. With a view of meeting this point, so far as can properly be done, the Board have decided to vary the provisions of the Order, so that in certain cases of the kind the certificate of proficiency may be obtainable by a practitioner after examination only and without a special course of instruction immediately before the examination.

The "certain cases of the kind" are defined as follows; such certificates may be issued—

> (*a*) To any registered medical practitioner who possesses a diploma, licence, or degree conferring the right of registration under the Medical Acts, and granted by an examining body in England and

> Wales or Scotland prior to the date at which the examining body first required, as a condition of obtaining the diploma, licence, or degree, a certificate of proficiency in vaccination given by a person authorised by us to act for the purpose; and (b) to any registered medical practitioner who possesses a diploma, licence, or degree which confers the right of registration under the Medical Acts and which has been or may be granted by an examining body in Ireland, before Jan. 1st, 1906.

The circular accompanying the Order gives the names of persons who have been authorised by the Local Government Board to give certificates after examination only and the stations where such examinations are held. They are eight in number, situated respectively in London, Birmingham, Bristol, Liverpool, Newcastle-on-Tyne, Aberdeen, Edinburgh, and Dublin. The London certificates after examination may be obtained at Tolmers-square Institute, Drummond-street, N.W.

WOMEN AS PHARMACISTS.

THERE can be no reasonable objection to the employment of women in pharmacy so long as they are duly qualified and the qualification of the Pharmaceutical Society to dispense medicines should be insisted upon as much in their case as in that of men pharmacists. Temptations there are, no doubt, open to qualified persons to offer their services to a company of unqualified persons in order to carry on for them a pharmaceutical business. The temptation has extended to women pharmacists and we learn that a company has been promoted with a qualified woman chemist and druggist on the directorate to conduct amongst other things a department of pharmacy. The real nature of the business may be gathered from the fact that "the other things" include the businesses of apothecaries (?), engineers, journalists, moneylenders, house agents, bill-posters, coal merchants, grocers, printers, dentists, and tobacconists.

THE LOCATION OF THE FIBRES FOR TEMPERATURE AND PAIN IN THE TRACT OF GOWERS.

MANY writers think that the sensations of pain and temperature are conveyed in the spinal cord by the tracts of Gowers but the evidence is not conclusive. In the *Journal of Nervous and Mental Disease* Professor W. G. Spiller has recorded a case which appears to give the best evidence yet offered of this view. A man, aged 23 years, came under observation on Sept. 1st, 1904. Four months previously he began to have pain in the lumbar region and abdomen. Soon numbness was felt in the feet and gradually involved the legs below the knees. There was extreme genu valgum which had existed for about five years. On the abdomen were scars which the patient said were due to painless burns in childhood. In the lower limbs resistance to passive movements was slightly diminished and sensibility to touch was normal or nearly normal, while sensibility to pain was abolished or almost abolished. Sensibility to temperature was almost lost below the knees and was much impaired in the thighs and lower part of the trunk. There was slight kyphosis about the tenth dorsal vertebra. After a fall backwards down a flight of steps the patient became completely paralysed in the lower limbs. Sensibility to touch was then lost in the right lower limb for a time. Sensibility to temperature and pain was absent in the right leg and foot and in the left foot. The knee-jerks were increased and Babinski's sign was present. Later sensibility to touch was found everywhere in the lower limbs and sensibility to pain was irregularly present, the response being very uncertain, and sensibility to temperature was much impaired. The patient died four months after the accident. The necropsy showed tuberculous meningitis and caries of the vertebræ and a small tubercle in the right lateral column at the lower end of the thoracic cord involving Gowers's tract. About an inch higher another small tubercle was found involving the left tract of Gowers. There was some myelitis which evidently had chiefly developed after the fall, for previously the weakness in the lower limbs was slight.

CONVERSAZIONE AT UNIVERSITY COLLEGE, LONDON.

A RECEPTION and conversazione were held at University College, Gower-street, W.C., on June 28th. The proceedings were a great success and there was a large company present attracted by the excellent programme provided and the specially interesting character of the scientific exhibits. The visitors were received on the grand staircase by the Treasurer, the Principal, the Dean of the Faculty of Arts and Laws, the Dean of the Faculty of Science, the Dean of the Faculty of Medicine, and the President of the Union Society. Amongst the exhibits which excited considerable interest were Professor J. Norman Collie's Chinese and Japanese art collection; antiquities from Egypt and Sinai, by Professor Flinders Petrie; radio-active phenomena, by Sir William Ramsay; mathematical instruments and models, by Professor Karl Pearson; trypanosomata, by Dr. D. N. Nabarro and Dr. T. H. C. Stevenson; and a botanical collection, by Professor F. W. Oliver. During the evening short lectures were given with lantern illustrations. The occasion provided a perfect feast of things literary, historic, artistic, and scientific.

PROPOSED NATIONAL LEAGUE FOR PHYSICAL EDUCATION AND IMPROVEMENT.

A DINNER was given at the Hotel Cecil on June 24th under the chairmanship of the Bishop of Ripon, a number of representatives of the press throughout the country being invited to meet the members of the proposed National League for Physical Education and Improvement. After the usual loyal toasts, "Success to the Proposed National League" was proposed by Sir Henry Craik, K.C.B., who referred to the objects of the movement and to the part played by Sir Lauder Brunton in its inception. General Sir Frederick Maurice, K.C.B., in proposing the toast of "The Press," appealed to the patriotic and altruistic sentiments of those members present to help forward the movement, which was one of truly national importance. Sir Hugh Gilzean-Reid, in reply, recognised the importance of the work proposed to be undertaken by the League and foretold success for it. In reply to the toast of his health, proposed by the Rev. Russell H. Wakefield, Mayor of Marylebone, the Bishop of Ripon referred in eloquent words to the need for such a movement and the useful part the League could play in correlating and extending existing agencies, in promoting the best interests of the nation and improving the standard of national health and physique. The objects of the proposed League are such that all medical men will wish it hearty success and the need for its existence is emphasised by the report of the interdepartmental committee and by the percentage of rejections of those offering themselves for military service.

WE regret to announce the death of Surgeon-General James Macnabb Cuningham, C.S.I., I.M.S., Honorary Surgeon to the King, which took place on June 27th; and of Inspector-General Alexander Turnbull, R.N. (retired), at the age of 67 years, on June 22nd. Inspector-General Turnbull, as staff-surgeon of the *Bacchante* in 1880–82, was in medical charge of the late Prince Albert Victor Duke of Clarence and of Prince George (now Prince of Wales) on board that vessel.

THE distribution of prizes to the students of St. Bartholomew's Hospital will be held in the great hall of the hospital on Wednesday, July 12th, at 3.30 P.M. The prizes will be distributed by the Right Honourable Lord Ludlow.

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER XVIII.[1]

THE PUBLIC AND THE MEDICAL PROFESSION.

Bad Effects of the Want of Concord among Medical Men.—Medical Etiquette and Medical Ethics.—The Public Conception of Medical Duties.

IT is an especially unfortunate commentary upon the great good which would follow upon medical organisation that at the present moment certain sections of the medical profession should be, or should so often appear to be, directly pitted against each other. There is a tendency on the part of certain general practitioners whose grievances are undoubtedly the hardest to bear to regard consulting practitioners and the General Medical Council, acting separately or in combination, as their natural enemies. They consider and write that "the prestige of the general practitioner has been lowered" because from the many circumstances which have been narrated his emoluments have decreased. This is a most unlucky use of the word prestige, the only lowering of prestige that has taken place being that which must follow upon the public exhibition of professional bad feeling. The general practitioner has the sympathy of all the profession who see him preyed on by quacks and irregular workers in medical fields and they are only opponents to reform—that is, they perpetuate the bad things now existing—who represent all consulting medical men and all public medical officials as the oppressors of the general practitioner, or who suggest that the General Medical Council has no care for his wrongs.

There are unscrupulous consultants who do their calling, as well as the public, great disservice by endeavouring to remain in sole attendance upon patients who have been brought to their attention by general practitioners. Any attempt to undermine the confidence of the public or to supplant the general practitioner will surely bring the system under which the family medical adviser is wont to obtain an independent and perhaps specialised opinion upon a difficult case into disrepute. The public is so largely a gainer by the readiness with which medical men, as a rule, are willing to submit the diagnosis and treatment of cases under their charge to the critical inspection of their colleagues, that the consultant practitioner who attempts to secure a patient for himself, by replacing the family man who first introduced the patient to him, not only commits a dishonourable act but injures the public in a very direct manner. The position so seldom arises that to describe the consulting medical man as living by piratical excursions into the territory of his brethren is ridiculous, and mischievous as tending to lower the public estimate of the medical profession. The same may be said of violent diatribes against medical officers of health and public vaccinators. Undoubtedly both the medical officer of health and the public vaccinator are by the circumstances of their offices sometimes placed in an antagonistic position to the general practitioner, but these are matters to be discussed temperately with a view to their amendment and not to be accepted in a sweeping way as proofs that the general practitioner is wantonly maltreated by his fellows. The monopoly which has been created in behalf of the public vaccinators is unfortunate and there is no reason why it should not be done away with, but to effect this arguments will have to be employed. The bald statement that public vaccinators receive fees which should be shared among their brethren cannot possibly stir any legislature to action, while not to recognise the arduous, delicate, and valuable work that is being done by public vaccinators is blind—as blind and ignorant as it is to represent all public vaccinators as overpaid plutocrats. The medical men who talk in this way and who regard more temperate views as cowardly are committing a serious error. At a time when there are many real and necessary reforms awaiting initiation they insult the intelligence of those who might be willing to help.

The growth of a general desire among medical men to form a united profession must occur before many of the disabilities under which the profession lies will be removed, but it is certain that the public would more often be on the side of the medical man in his demands for intelligent and sympathetic treatment if the public had a clearer conception of his difficulties. Next to union among medical men public sympathy is required. The various circumstances which conspire to press hardly in different ways upon different sections of the profession are not in the least understood by the public, who regard anything in the nature of a cry for reform among medical men either as a proof that the ranks of the profession are overcrowded or as a design upon the part of certain operatives, banded together by a mysterious tie called medical etiquette, to strike for higher pay. With respect to the alleged overcrowding of the medical profession the figures, already quoted,[2] show that there is misconception on this point. There are too many medical men in certain places trying to do the same thing—that is to say, that the distribution of medical men is faulty both as regards their economic position and as regards their public utility—but the numerical ratio of the population to the medical profession has not fallen. And similarly it is a grave mistake to suppose that the members of the medical profession are in corrupt league to extract money out of the public, though it is not difficult to see how this conception had origin. The most evident examples of union among medical men have been the local combinations to resist the tyranny of medical aid associations and of workmen's clubs. The battle having been fought in these cases largely upon the question of remuneration the public has been led to believe that this is the only question at issue and does not see the underlying difficulty, viz., that the lay employer—whether this be a Government department, a municipality, or a miner's foreman—frequently fails to regard medical service as in any way differing from the service of the tradesman in response to a wage. There are coroners of the same turn of mind who regard the wish of medical men to give evidence where it would conduce to the return of a just verdict as proof of hunger for a fee; and there are barristers and even judges who consider that every expression of opinion from a medical witness must be made in deference to his retainer as an expert. Judges, barristers, and coroners give voice to these views, certain journals give prominence to them, and lo! there is the medical profession branded as a venal association that is ever working for its own aggrandisement against the public weal. What reform would such a profession be likely to ask for save such as would put money in its purse?

The deduction is fair enough but it is made from an incorrect observation of facts. What, then, is medical etiquette? It is the behaviour entailed upon medical men by the observance of medical ethics, and the rules regulating medical conduct are designed with a view of marking the difference between the profession of medicine and a trade. There is no need more than to indicate the distinction, for the comparison has been drawn so frequently. A profession and a trade have this in common—each is a vocation in which a man seeks to make a livelihood by serving the public. But in trade the rivals can compete for public favour by asserting that their methods of ministering to their clients are better than those of others following the same calling. They can do this without taking an unfair advantage of the public, for the public can judge whether the wares sold to them are what they want, are up to sample, and are in accordance with advertised claims. In a profession these assertions cannot be made without a risk of deceiving the public, because the public cannot judge of their truth. The specialised work of a medical man cannot be gauged by any who have not special knowledge, so that for the protection of the public medical men have agreed not to make any public claims to skill or learning. In this way the loud pretender is, at any rate to a great extent, defeated, but from this situation arises the fact that medical men must trust each other a great deal and must maintain between each other a high code of honour. They must treat each other as they would be treated.

The public belief that medical men are guided in their behaviour by a set of quaint and secret rules designed to maintain medical interests at the expense of the popular purse receives confirmation from the fact that many medical men appear to want to regulate their conduct towards each other and towards the public by some elaborate code which shall meet any professional difficulties that may arise. They do not find it a sufficiently explicit position merely to say that obedience to the dictates of medical ethics implies application to the ordinary chances of professional life of the excellent rule that a man should do as he would be done by. If only medical men and the public would see that the gist of medical ethics lies in that sentence the medical attitude in public affairs would be better comprehended. Aphoristic by-laws designed to meet special cases are often useful and it is not intended to decry the value of one or two codes of ethics that have been published, but such books are likely to mislead the professional man as much as the public, if their limitations are not recognised, by causing both to think more of special instances than of general principles. Take, for example, this common situation. A medical man is in attendance upon a patient and the patient desires to discharge him and to employ somebody else. The patient finds that there is difficulty in obtaining the service of the second medical man who, though prepared perhaps to assist in any acute emergency, declines to take over the case save from the hands of the previous medical man. The patient complains that obstacles are placed in the way of his obtaining the medical advice that he wishes to have, and blames "medical etiquette." His view is supported by the unfortunate circumstance that many medical men write and speak as if they believed that, having once been called in to see a patient, they had obtained a vested right in that patient and could on no account be dislodged from his bedside. Now clearly a patient has the right to see whatever medical man he likes, but it has been thought advisable by the medical profession, in the interests as much of the patient as of the medical man, to lay it down that a second medical man should not attend until the first medical man has been definitely discharged from the case, when the second medical man would receive from the first medical man a statement of the circumstances. The reason for this is obvious. The patient being without medical learning cannot know that the treatment, which is apparently doing him no good, is the wrong treatment, and cannot tell a second medical man even what that treatment has been. If the second medical man does not consult with the first he is treating the case without being in possession of the facts necessary to make a diagnosis. If the case goes well he will obtain credit at the expense of a brother practitioner which he may not deserve, and mark—he will obtain the credit even though he repudiates its justice. If the case goes ill it will be considered that the preliminary mismanagement of the first medical man had dictated the bad issue. Now let the second medical man consider whether he himself would like to be placed in the position in which the patient has placed the first medical man. This is but one example of situations that may arise by the score and most the others can be similarly solved by the simple application of the same rule. A code-book undoubtedly has its uses if too much is not expected of it, but however well drawn up it may tend to elaborate and to obscure what should be simple, while any attempt to meet all cases by special decisions must fail. As life in general gets more and more complicated it becomes more and more impossible to lay down cut-and-dried rules to meet all sorts of emergencies.

---

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., XVI., and XVII. were published in THE LANCET of Feb. 18th (p. 447) and 25th (p. 517), March 4th (p. 593), 18th (p. 736), and 25th (p. 817), April 1st (p. 877), 15th (p. 1017), 22nd (p. 1089), and 29th (p. 1151), May 6th (p. 1218), 13th (p. 1287), 20th (p. 1375), and 27th (p. 1449), June 3rd (p. 1533), 10th (p. 1584), 17th (p. 1651), and 24th (p. 1741), 1905, respectively.

[2] See Chapter III.

The belief that the medical profession is governed by a set of rules framed with a special design to exploit the public is blended in the public mind, to the detriment of the profession, with a very different idea. The public conceives that medical service must be in a sense a poor thing because so much of it is rendered gratuitously. The public view—at any rate the view of the poorer section of the public—of the connexion of a member of the medical staff of a hospital with his institution is a comically paradoxical one. First it is thought that the medical officer is paid for his work and is greedy to make money out of the afflictions of his fellows. On learning that he is not paid at all the public at once thinks meanly of his exertions, not being able to understand that good work can be unpaid work. It is not understood that gratuitous work is done by medical men because the experience so gained is valuable to mankind and because only in this way can material for scientific progress be obtained, every whit as much as because, without the experience furnished by hospital wards, few medical men can become great and very few can become successful. Legitimate ambition and legitimate desire to be properly paid for good work play their part in inspiring the honorary staffs of our great free hospitals, for the value of the hospital connexion is realised to its full; but the desire to increase the stock of the world's wisdom and to decrease the sum of human misery, the love of science for itself and affection for the medical profession,—these things also confirm medical men in their willingness to serve the sick poor without reward in money, indeed at a vast expense of valuable time and knowledge. This is the professional conception of the situation and it should be understood by the public.

But undoubtedly those who see in this altruism of the medical profession a confession of weakness, and who are influenced accordingly to treat the members of the medical profession as of no particular account, receive from other circumstances frequent support. For it is not only the member of the hospital staff who works for nothing but all medical men are constantly serving the public gratuitously. The General Medical Council, which does work of paramount importance to the State, receives no subsidy whatever from the State and has accordingly been in considerable pecuniary trouble. When the country decided that the registration of midwives was necessary machinery in the shape of the Midwives Board was devised for the proper examination of candidates, for maintaining an official roll of the women, and for exercising disciplinary powers over them. In the constitution of the Midwives Board every precaution was taken to guard the interests of the public and to secure fair play for the registered midwife, but there was no provision made for paying the Midwives Board. The work is done for the State by busy medical men and busy public-spirited women and should be paid for by the State. Again, under the Midwives Act the midwives are in certain circumstances required to seek medical coöperation, but the Act contains no provision for the payment of the medical man, it being apparently taken for granted that he will give his services if the patient cannot afford to pay. The same thing is seen throughout our social scheme, the same very flattering but very embarrassing reliance upon the altruism of the medical profession, and so much has it become the spirit of medical men to give their work away that even such a protest as I am now making will be voted vulgar and "tradesmanlike" by some superior spirits. Why should a medical man be expected to sign dozens of gratuitous certificates? School boards want certificates to explain the absence of their scholars, sick clubs want certificates to guide them in making allowances to their members, life assurance offices want certificates to assist their regular officers to estimate risk; in the last case a minute fee is usually proffered by the office when it is not possible to make the proposer for a policy pay, in the other cases the work is done by the medical profession for nothing. I say "the work" advisedly, for sometimes the filling up and signing of these certificates wastes a serious amount of time and involves considerable writing. All such sick certificates should be paid for either by the persons who want to show them or by the persons who insist upon their being shown. It would be logical to go further and say that death certificates should be made the subject of a fee to medical men. There would be in some respects difficulty in supporting this claim but we may be perfectly certain that nobody but a medical man would ever be expected to give death certificates for nothing. The copies of them, which are not made by medical men, are subject to a fee.

In all public affairs parsimony towards the medical man exists. The scale of remuneration of medical witnesses is ridiculously low. This is acknowledged by everyone but as yet there has been no remedy. Municipal bodies, whose spendthrift policy in every direction is notorious, frequently attempt to get their official sanitary work done on the cheap; a certain class of coroner delights in dispensing with the attendance of a medical man at inquests, alleging with perfect gravity his position as guardian of the public purse in extenuation of his recklessness. Yet surely anyone who thinks must see that the cause of economy is not really served by making the busy medical man unable, save by fining himself a substantial sum of money, to give evidence in a law court, nor by sweating the man on whom the public health of the community exists, nor by increasing the inevitable percentage of unjust verdicts delivered by coroners' juries. Not long ago it was proposed in a certain rural sanitary district that measles should be raised to the dignity of a notifiable disease, when the rural council in a light-hearted manner resolved to call upon the medical men of the neighbourhood to notify all cases occurring in one household for one fee. The first idea of the authority, in making a proposal believed to be for sanitary progress, was to save a part of the money due for the sanitary assistance of medical men! Why should the first idea of a public body planning a development under an Act of Parliament be to invite the medical practitioners of the neighbourhood to break the law with the view of receiving smaller fees than Parliament has awarded them? Why? First, because it is ingrained in public bodies to try to get medical assistance for nothing; and secondly, because the public, knowing nothing whatever of the details of medical life, believes that an epidemic of measles brings a fortune to the medical men of the neighbourhood. Medical men in a rural district do not make money by the prevalence of measles; on the contrary, an epidemic may leave them out of pocket. Their work is enormously increased but the remuneration, though in the aggregate larger, does not keep pace with the increased expenditure. This is not a theory, it is a fact, and one that it would be just of the public to remember.

I will give one more example of popular misunderstanding of the position of a medical man. It frequently happens that a medical man cannot come to a patient when he is summoned. Sometimes he is under an engagement to go elsewhere at too short an interval, sometimes he is too fatigued, sometimes he declines to come unless his fee is paid. If, unfortunately, the patient dies a coroner's jury almost invariably censures the medical man, the coroner frequently allows them to do so without protesting, and many newspapers, especially those that are conspicuous for printing the indecent advertisements of quacks, join in denunciation of the "callous doctor." In a moment a citizen who perhaps does more work for the public at a low rate of remuneration than anyone else in the community finds to his bewilderment that the simple exercise of his right to attend a case or not has earned him the reputation of a Nero in the neighbourhood. The rider of an ill-informed jury charges him with gross inhumanity in not attending the patient or holds him up to odium because he wanted to be paid for his onerous services. Yet if members of the public would only think they would detect the gross injustice of such a proceeding. In every instance where to do so is a matter of real urgency the medical man goes if possible wherever and whenever he is summoned, and it is a distinct hardship upon the medical profession that the contrary opinion should be held. Although a large proportion of a medical man's practice is unpaid, yet, when it is made clear to him that he is wanted to stand between death and a fellow creature, he goes. He does not think of his fee, he goes. He does not think of his convenience, he goes. But where the imminence of the case is not made clear he does not necessarily attend without a fee. It is not only unfair to expect the reverse but—and this is the point on which emphasis should be laid—it is unfair to those of the community who do pay their medical man that he should be at the beck and call of those who do not. A medical man has rarely any spare time and every extra visit made means a visit the less in some other direction. When a witness at an inquest tells of "a cruel doctor who wouldn't come until his fee was paid down," inquiry (which is so rarely made) would almost invariably elicit that the serious nature of the case had not been made clear.

It would not be difficult to continue to give instances showing that the medical profession does not obtain fair play at the hands of the public, but I think it may be taken as established that such is the case. These things are not narrated in any spirit of grumbling—there has been too much grumbling among medical men. They are set out as indications that the medical profession is very much misunderstood by the public and it seems to me that no effort should be spared to alter this state of affairs. The formation of local medico-ethical societies or the discussion of ethical affairs at local medical societies appears to be the best way of arriving at the solidarity of opinion that must necessarily be a prelude to any real and substantial reform. Such debates might also afford an opportunity of clearing up many points of difficulty, for removing many causes of friction between the medical profession and the public. On nursing questions, on question of hospital administration, on such social questions as the promotion of temperance and the prevention of racial deterioration medical men and laymen constantly confer and with mutual advantage. The assistance of laymen at debates upon questions of professional ethics might be useful; the good feeling evinced by such invitations and acceptations would certainly be very valuable.

If the first step towards the reform of the admitted abuses in the medical profession is the establishment of solidarity among medical men the second is the establishment of confidence between the medical profession and the public. When these two consummations exist reform will be imminent.

(To be continued.)

EPSOM COLLEGE.

THE annual general meeting of the governors of Epsom College was held at the office in Soho-square on Friday, June 23rd, the treasurer, Sir Constantine Holman, M.D., being in the chair. He was supported by a large number of governors, including Sir William Church, Bart. (the chairman of the council), Sir Arthur T. Watson, Bart., K.C., Mr. J. Paul Bush, C.M.G., Mr. G. H. Makins, C.B., Mr. John H. Morgan, C.V.O., Mr. Reginald Harrison, Dr. P. W. Latham, Dr. F. Needham, the Rev. E. W. Northey, and Dr. J. Roberts Thomson. The scrutineers (Dr. Roberts Thomson, Dr. Needham, and Mr. Makins) reported the result of the voting for pensioners and foundation scholars to be as follows:—

PENSIONERS.

Name.	Votes.	Name.	Votes.
1. Mary A. Paul	6370	3. Catherine Reese	5887
2. Mary Sewell	6052	4. Elizabeth Matthews ...	5766

FOUNDATION SCHOLARS.

Name.	Votes.	Name.	Votes
1. Kenneth T. K. Wallington	9147	5. William O. Deacon ...	8324
2. Robert K. MacRoberts...	9058	6. Ronald H. Kershaw ...	7505
3. Bernard S. Pullan... ...	8990	7. Bernard S. Lidiard ...	6352
4. Royale S. Dutton... ...	8867	8. Alexander L. H. Ferguson	5118

The report of the council stated that in order to bring the sanitary arrangements of the College into accordance with modern requirements it had been necessary to undertake works which would probably cost in the aggregate from £4000 to £5000. This very large outlay was to a great extent the result of the imperfect system of laying drains which was in vogue many years ago, and of the omission to remove from the ground disused drains, some of which might ultimately be a source of danger. Moreover, the ventilation of the drains and many of the sanitary fittings needed amendment. As the council deemed it unwise to part with any of the stock belonging to the general purposes fund, it had decided early in the present year to increase the mortgage on the College property from £10,000 to £14,000. Attention was drawn to the fact that the annual general meeting had this year been convened a month later than usual, in order to enable governors who live abroad to vote at the annual election of pensioners and foundation scholars. The council noted with much pleasure the large increase in the number of governors, both annual subscribers and life donors, who reside abroad. Two alterations in the by-laws to be proposed were referred to, one of which will be of great interest to supporters of the charitable side of the institution. Hitherto a donation of ten guineas has had to be given in not more than two payments in order to entitle the donor to be registered a life governor. The council suggested that the stipulation of two payments should be done away with, which will enable one vote for life to be given for each sum of ten guineas, in however many separate sums the money is presented. The council was glad to be able to report satisfactorily on the school, the health of the boys having been on the whole good, the discipline having been excellent, and the usual school games having been played with success. The rifle corps continued to be most successful and the natural history society and other school institutions were flourishing. Nine boys had since the last general meeting passed the whole or a part of the preliminary scientific examination for the degree of M.B., B.S., of the University of London: four boys had passed the University of London matriculation examination in Division 1 and seven in Division 2; seven boys had gained the higher certificate of the Oxford and Cambridge schools examination board with one distinction and 17 had gained the lower certificate; seven boys had gained the second-class certificate of the College of Preceptors, two boys had obtained the first class certificate for drawing (freehand and model) in the art examinations held under the direction of the Board of Education, and seven had obtained the second-class certificate. After careful inquiry the council had inaugurated a pension scheme by which the assistant masters at the College would have suitable provision made for them at the age of 60 years.

In moving the adoption of the report Sir Constantine Holman referred to the fact that this was the jubilee year of the opening of the College and he expressed the opinion that the founder of the College, the late Mr. John Propert, would have been in every way satisfied with the work as at present carried out, and the late Mr. Lumsden Propert, his son, had held the same opinion. He referred to the never-ending appeals which were necessary in order to continue in full the work of the benevolent side of the College, which required a sum of about £8000 a year, and gave in detail the sums which had had to be spent to maintain buildings at Epsom in proper repair. Having referred to the great services which Sir Joseph Fayrer had rendered for so many years as chairman of the council he congratulated the governors on having secured the services of Sir William Church. He stated that the council had recently decided to follow the example of most of the public schools of the country by giving all the boys meat breakfasts and this alteration had been in force during the current term. In conclusion, he referred to the remarkable result of the voting for pensioners and foundation scholars, 11 out of the 12 candidates recommended as the most urgent cases by the selection committee having been elected.

The report was duly adopted, and other formal work having been carried out, Mr. Stamford Felce, who recently resigned his seat on the council, was elected a vice-president in recognition of his services for many years as a member of the council and as chairman of the finance and selection committees. In moving a vote of thanks to the chairman Sir William Church observed that Sir Constantine Holman had had one wish realised in the change of the official name of the institution to "Epsom College," and he hoped that he would soon have his two other wishes granted—namely, that the institution should be free from debt and that the College should be full.

At the meeting of the council held subsequently Mrs. Swales, the highest on the list of unsuccessful candidates for pensionerships, was elected a pensioner, a vacancy having arisen, and Dr. William Collier, President of the British Medical Association, was elected a member of the council.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 30, 1827.

HOUSE OF COMMONS.

Wednesday, June 20, 1827.

ROYAL COLLEGE OF SURGEONS.

Mr. WARBURTON presented a Petition from the Royal College of Surgeons, complaining of the Regulations of the College. Ordered to be printed.

Mr. WARBURTON proceeded to make the motion of which he had given notice, respecting the Royal College of Surgeons. He observed that, all the evils which usually resulted from a close corporation of any kind, had manifested themselves in the Institution in question. The interests of the many were sacrificed for the benefit of the few. The enactments of the Corporation, of which the commonalty complained, were as follows:—In 1796, a former Corporation, out of which the present Corporation grew, was, in consequence of some irregularity, dissolved. In 1797, an application was made to Parliament for the purpose of establishing the Corporation anew; and a Bill was brought in for that purpose, granting the proposed Corporation many powers, among which was the extraordinary one of monopolising the lecturing on surgery in London, although at that very time many schools of surgery were in existence in the metropolis. After the Bill had passed through the House of Commons, and through several stages of the House of Lords, great secrecy being observed with respect to its provisions, this strange clause was at length discovered, and the Bill was immediately scouted, as it well deserved to be. In 1800, the College of Surgeons obtained their present Charter from the Crown. It was true that the Charter did not contain any such power as that involved in the clause which he had just described; but the College endeavoured, by means of by-laws, to obtain a similar authority. The evil was, that the individuals of whom the Council of the College consisted, were, more or less, connected with the Hospitals, and with the lectures delivered in those Hospitals; and therefore had a direct interest in framing the by-laws in question. By those by-laws it was declared, that the only regular schools of anatomy and surgery were the hospitals of London, Dublin, Edinburgh, Glasgow, and Aberdeen; that no certificate of a pupil could be received unless he had studied in one of the above, containing a hundred patients, for a year; or in a provincial hospital, containing the same number of patients, two years. It was well known, that in the provincial hospitals it was exceedingly difficult to obtain subjects. London, Dublin, and Glasgow, were the only places in which they could be had with any facility. Formerly, it had been considered as the just reward of a surgeon who distinguished himself at the regular hospitals, that if he established himself as a lecturer in private, his class was likely to be numerously attended. It was not enough now, however, for a young man to produce a certificate of attendance on any of these gentlemen, or even of attendance at foreign hospitals; such as those of Paris, Vienna, &c. He had to complain on behalf of the petitioners, that the examinations by the College were private, and it would be readily conceded that great advantages were in almost all cases attendant upon publicity. The petitioners were no advocates for rendering admission into the profession more easy than it at present was, their object being only to make examinations more fair, and the persons admitted more highly qualified for the duties they would be called upon to perform. The examiners were at present appointed for life; and it happened that the science often got the start of them, and they were behind the knowledge which their younger contemporaries possessed. The examinations were often of a very superficial description; and the Admiralty and Military Boards were so dissatisfied with the examinations of the College, that they were obliged to subject persons to a further scrutiny, to ascertain whether they were fit for the public service. It was considered by the College, that all persons who practised the obstetric branch of the profession, as well as all apothecaries, were less qualified than others for the honours and advantages of that institution. Another complaint was, that the College had passed a by-law, which required every student, before examination, to produce a certificate that he had attended a course of winter lectures. This extraordinary by-law was not confined merely to dissection, but it extended to surgery and anatomy. This was the means of depriving of pupils, and consequently of suppressing the lectures which many able men had been accustomed to give in the summer. It was justly complained that the College had made an invidious distinction as to the entrance granted to members and to students into the Theatre. The Museum was opened only twice a week, and then only two hours on each day. This museum was purchased in 1799, and was removed to its present place of accommodation in 1806, and yet no catalogue of its contents was published, and the collection was consequently rendered useless. At the time of making the purchase, the collection contained many MS. of the late John Hunter; and these, from a certain degree of neglect in the council, had been suffered to be destroyed. He regretted that it was now too late to refer these matters to a committee of the house. At an early period of the next session, if the petitioners continued in the same mind as at present, he should certainly move for a committee to inquire into the subject. In the meantime he should move for certain papers, which would afford the necessary information for the guidance of the house. The honourable member concluded by moving for a return from the College of Surgeons, of all public money lent or granted to the College from 1799 to the present time, for the purchase of the Hunterian Museum, and for building, purchasing, repairing, and improving the said College, with the appropriation and expenditure thereof—the regulations under which the members and students are admitted to the

Hunterian Museum, and to the Library of the College—the number of persons examined for practice in surgery—and an account of all moneys received by the College in 1825 and 1826, on account of the members.[1]

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9369 births and 3877 deaths were registered during the week ending June 24th. The annual rate of mortality in these towns, which had been 14·7, 13·5, and 13·4 per 1000 in the three preceding weeks, further declined last week to 13·0 per 1000. In London the death-rate was 11·7 per 1000, while it averaged 13·5 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·7 in Wallasey, 6·8 in Hornsey and in Handsworth (Staffs), 7·4 in Croydon, 7·6 in Tottenham, 8·2 in King's Norton, 8·3 in Willesden, and 8·6 in Southampton; the highest death-rates were 18·1 in Sunderland, 18·4 in Ipswich, 18·5 in Burnley and in Tynemouth, 20·3 in Preston, and 24·2 in Oldham. The 3877 deaths in these towns last week included 348 deaths which were referred to the principal infectious diseases, against 410, 413, and 355 in the three preceding weeks; of these 348 deaths, 127 resulted from measles, 74 from whooping-cough, 67 from diarrhœa, 39 from diphtheria, 23 from scarlet fever, and 18 from "fever" (principally enteric), but not any from small-pox. In Croydon, Leyton, Hastings, Brighton, Norwich, Walsall, Stockport, Huddersfield, and in 11 other smaller towns, no death from any of the principal diseases was registered last week; they caused the highest death-rates in Walthamstow, Northampton, West Bromwich, Coventry, Bootle, Sheffield, and Sunderland. The greatest proportional mortality from measles occurred in Northampton, West Bromwich, Smethwick, Coventry, Barrow-in-Furness, Sheffield, and Sunderland; from scarlet fever in Bootle; from diphtheria in East Ham, Middlesbrough, and South Shields; from whooping-cough in Walthamstow and Oldham; and from diarrhœa in Hanley, Wigan, and Blackburn. The mortality *from "fever"* showed no marked excess in any of the large towns. No death from small-pox was registered either in London or in any of the large provincial towns. The number of small-pox cases remaining under treatment in the Metropolitan Asylums Hospitals, which had been nine, nine, and seven at the end of the three preceding weeks, had further fallen to six at the end of last week; one new case was admitted during the week, against one, three, and three in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday, June 24th, was 2427, against 2268, 2285, and 2356 on the three preceding Saturdays; 325 new cases were admitted during the week, against 351, 269, and 292 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory organs, which had been 235, 191, and 189 in the three preceding weeks, further declined to 144 last week, but were three above the number in the corresponding period of last year. The causes of 55, or 1·4 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Leicester, Salford, Bradford, Leeds, and in 41 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn, Preston, Barrow-in-Furness, Sheffield, Sunderland, Gateshead, and Newcastle-on-Tyne.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 16·9, 16·4, and 15·7 per 1000 in the three preceding weeks, further declined to 15·1 per 1000 during the week ending June 24th, but was 2·1 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 9·6 in Leith and 11·8 in Aberdeen to 16·8 in Perth and 18 6 in Greenock. The 508 deaths in these towns included 18 which were referred to measles, 18 to whooping-cough, 15 to diarrhœa, four to diphtheria, three to "fever," and two to scarlet fever, but not any to small-pox. In all 60 deaths resulted from these principal infectious diseases last week, against 80, 62, and 74 in the three preceding weeks. These 60 deaths were equal to an annual rate of 1·8 per 1000, which was 0·6 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 33, 17, and 26 in the three preceding weeks, declined again last week to 18, of which 12 occurred in Glasgow, four in Edinburgh, and two in Perth. The deaths from whooping-cough, which had been 24, 23, and 29 in the three preceding weeks, decreased to 18 last week, and included 11 in Glasgow, three in Edinburgh, and three in Dundee. The fatal cases of diarrhœa, which had been 16, 14, and 15 in the three preceding weeks, were again 15 last week, and included eight in Glasgow, three in Edinburgh, and three in Aberdeen. The deaths from diphtheria, which had been one, four, and one in the three preceding weeks, rose again last week to four, of which two occurred in Glasgow. The fatal cases of "fever," which had been three, three, and two in the three preceding weeks, rose again to three last week and included two, one being a case of typhus, in Greenock. The deaths referred to diseases of the respiratory organs in these towns, which had been 88, 89, and 63 in the three preceding weeks, rose again last week to 74, and were 10 in excess of the number in the corresponding period of last year. The causes of 22, or more than 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·4, 19·3, and 17·2 per 1000 in the three preceding weeks, rose again to 17·9 per 1000 during the week ending June 24th. During the past four weeks the death-rate has averaged 18 5 per 1000, the rates during the same period being 13·4 in London and 15·9 in Edinburgh. The 130 deaths of persons belonging to Dublin registered during the week under notice were five in excess of the number in the preceding week and included six which were referred to the principal infectious diseases, against eight, five, and three in the three preceding weeks; of these, two resulted from measles, two from diarrhœa, one from diphtheria, and one from "fever," but not any from small-pox, scarlet fever, or whooping-cough. These six deaths were equal to an annual rate of 0·8 per 1000, the death-rates last week from the principal infectious diseases being 1·2 in London and 1·7 in Edinburgh. The 130 deaths in Dublin last week included 21 of children under one year of age and 37 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons were considerably in excess of the respective numbers recorded in the preceding week. Six inquest cases and four deaths from violence were registered; and 52, or two-fifths, of the deaths occurred in public institutions. The causes of six, or nearly 5 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: D. D. Turner to the *Pembroke* for disposal; A. C. Bean to the *Egmont* for the *Maine;* and P. T. Nicholls to the *Thetis.*

ARMY MEDICAL STAFF.

Surgeon-General W. F. Burnett is placed on retired pay (dated June 21st, 1905).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Majors are placed on retired pay (dated May 30th, 1905): Arthur O. Fitzgerald, Frederick D. Elderton, and Robert I. Power.

INDIAN MEDICAL SERVICE.

The undermentioned Lieutenant-Colonels to be Colonels: Roderick Macrae (dated Feb. 12th, 1905) and Robert D. Murray (dated March 29th, 1905).

---

[1] The Editor states in a leading article in the same issue of THE LANCET that he has purposely selected the reports of the speeches from the daily press and that Mr. Warburton's speech is taken from the *Chronicle* and Mr. Peel's from the *Times*. The speeches by Mr. (Sir Robert in May, 1830) Peel, ex-Home Secretary, and by Mr. W. Smith and Sir Joseph Yorke have not been transcribed. The report concludes as follows: "After a few words from Lord Binning, Mr. H. Gurney, Mr. Maberly, Mr. Secretary Bourne, and Mr. Warburton, the motion was put and agreed to."

ARMY MEDICAL RESERVE OF OFFICERS.

Lieutenant J. S. Warrack, Royal Army Medical Corps (Volunteers), to be Surgeon-Lieutenant (dated June 24th, 1905). Surgeon-Major E. T. Crouch to be Surgeon-Lieutenant-Colonel (dated June 20th, 1905). Surgeon-Captain H. Dickie to be Surgeon-Major (dated June 17th, 1905).

ROYAL ARMY MEDICAL CORPS (MILITIA).

Welsh and Midland Command: Lichfield Company: Lieutenant (Honorary Lieutenant in the Army) H. J. L. Bullen to be Captain (dated Feb. 26th, 1905). Irish Command: No. 3 Belfast Company: The promotion to the rank of Captain of Lieutenant (Honorary Lieutenant in the Army) S. T. Beggs bears date June 19th, 1904.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Suffolk and Harwich: Surgeon-Captain T. E. Stuart to be Surgeon-Major (dated Nov. 26th, 1904). 2nd East Riding of Yorkshire: Surgeon-Captain J. Soutter to be Surgeon-Major (dated June 24th, 1905).

Rifle: 1st Volunteer Battalion the East Yorkshire Regiment: Surgeon-Captain H. G. Falkner is borne as Supernumerary whilst attached to the Yorkshire Volunteer Infantry Brigade Bearer Company (dated June 24th, 1905). 1st Lanarkshire: Surgeon-Captain J. G. Andrew resigns his commission (dated June 24th, 1905). 1st Volunteer Battalion the King's (Shropshire Light Infantry): Surgeon-Major W. H. Packer is granted the honorary rank of Surgeon-Lieutenant-Colonel (dated June 24th, 1905). 17th (North) Middlesex: Surgeon-Lieutenant F. H. Gervis to be Surgeon-Captain (dated June 24th, 1905).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Northern Command: Manchester Companies: Lieutenant-Colonel W. Coates is granted the honorary rank of Colonel (dated June 7th, 1905). Eastern Command: Maidstone Companies: Lieutenant J. M. Rogers-Tillstone to be Captain (dated April 12th, 1905). Scottish Command: Aberdeen Companies: Surgeon-Lieutenant P. Mitchell, from the 5th (Deeside Highland) Volunteer Battalion the Gordon Highlanders, to be Lieutenant (dated June 10th, 1905). Scottish Command: Glasgow Companies: Lieutenant (Surgeon-Lieutenant, Army Medical Reserve of Officers) J. T. K. Thomson resigns his commission (dated June 10th, 1905). South Wales Border Bearer Company: Thomas Donovan to be Lieutenant (dated June 12th, 1905).

THE INDIAN ARMY COMMAND.

As our "service" readers are aware a serious official conflict of opinion has of late been taking place between the Viceroy of India and General Sir E. Elles, the military member of Council, on the one part and Lord Kitchener on the other with the result that a great and radical change is about to be carried out in our Indian military system. Substantially it is that proposed by Lord Kitchener and among other things it may possibly affect the position, although, as it appears to us, only nominally, of the Indian Medical Service. The Commander-in-Chief in India is henceforth to be recognised as the one military adviser of the Indian Government and is to be directly responsible for everything connected with war and the preparation for it. The Military Department, on the other hand, will be limited to the control of contracts and purchases, and the management of military works and of the increasing manufacturing departments, with charge of the Indian Medical Service and the Indian Marine. The business function of supplying the army with necessaries is henceforth to be kept altogether distinct from the military function of command.

THE ROYAL NAVAL HOSPITAL, STONEHOUSE.

A number of members of the St. John Ambulance Association at Bolton, who have engaged to serve with the sick berth staff of the Royal Navy in the event of war, are undergoing a week's training at the Royal Naval Hospital, Stonehouse (Plymouth).

DEATHS IN THE SERVICES.

Surgeon-General James Macnabb Cuningham, C.S.I., I.M.S., Bengal (retired), Honorary Surgeon to the King, on June 27th.

Inspector-General of Hospitals and Fleets Alexander Turnbull, R.N. (retired), on June 22nd, aged 67.

THE WAR IN THE FAR EAST.

There is no medical news connected with the war to be recorded this week. According to a Washington telegram the peace plenipotentiaries of the Japanese and Russian Governments will meet early in August but no action has yet been taken in regard to an armistice.

The *Maine* hospital ship arrived at Plymouth on June 23rd with invalids from the Mediterranean station. 20 medical and 13 surgical cases, together with one lunatic, were taken to the Royal Naval Hospital, Stonehouse.

The Army Council has decided that from July 1st all Staff and departmental officers serving at home and abroad (except India) shall, in common with regimental officers, have the option of drawing their pay either through the agents or through the local accountant or paymaster.

Correspondence.

"Audi alteram partem."

THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY: THE PRESIDENTS' PORTRAITS.

To the Editors of THE LANCET.

SIRS,—I am anxious, if possible, to complete our collection of portraits of past Presidents and should be very grateful to anyone who would put me in the way of making good our deficiencies. I subjoin a list of those Presidents of whom either we have no portraits or only very poor ones. While, of course, I should be glad to receive, and would gratefully acknowledge, gifts, I am quite willing to pay a fair price for any good portraits that may be offered to me.

I am, Sirs, yours faithfully,
J. Y. W. MACALISTER.

20, Hanover-square, W., June 23rd, 1905.

Portraits Wanted by the Royal Medical and Chirurgical Society.

"TRANSCENDENTAL MEDICINE."

To the Editors of THE LANCET.

SIRS,—"Cheops, M.B.," in his letter under this cryptic title raises questions of great interest for the general practitioner There is truth in his contention that we are apt to miss much of present-day thought by devoting a too-concentrated attention to our own voluminous and intricate subject. To a certain extent this state of matters is largely inevitable but that it should make us intolerant and narrow in ou outlook should not follow. That this danger threatens ha been made clear by your correspondent. Are we not apt t be too sectarian and to look with Philistine eyes upo those within and those without our cloisters who have bee so unorthodox as to cross the borderland and wander in un covenanted byways? In the empire of the intellect ther is no place for the "Little Englander," and it were a pity i such a spirit found disciples within our ranks. Have we a all times extended to the stranger within our gates tha intellectual hospitality which it is ours as a learned pro fession to proffer? While "Cheops, M.B.," hints that w have not always done so, other thinkers not of our craft ar quite sure about this point. They complain, to take a instance, of our impatience with any non-physiologic explanation of psychical phenomena.

Your correspondent makes mention of *Professor James* Gifford lectures. In his eulogy of them I heartily concu Professor James in his own breezy way hits off the situa tion thus: "We are all familiar in a general wa with this method of discrediting states of mind for whic we have an antipathy. We all use it to some degr in criticising persons whose states of mind we regar as over-strained. But when *other* people criticise our ow more exalted soul-flights by calling them 'nothing but' expressions of our organic disposition we feel outraged and hurt for we know that whatever be our organism's peculiarities our mental states have their substantive value as revelations of the living truth, and we wish that all this medical materialism could be made to hold its tongue." "Medical materialism," continues Professor James, "finishes up Saint Paul by calling his vision on the road to Damascus a discharging lesion of the occipital cortex, he being an epileptic. It snuffs out Saint Teresa as an hysteric, Saint Francis of Assisi as an hereditary degenerate. George Fox's discontent with the shams of his age and his pining for spiritual veracity it treats as a symptom of a disordered colon. Carlyle's organ-tones of misery it accounts for by a gastro-duodenal catarrh. And medical materialism then thinks that the spiritual authority of all such personages is successfully undermined." Many of us must feel grateful to "Cheops, M.B.," for the warning he has sounded. We shall be aided in our endeavour "to sometimes take a glance at the country round about" by a more diligent perusal of THE LANCET where this very grace of intellectual hospitality abounds.

I am, Sirs, yours faithfully,
W. E. HENDERSON.
June 19th, 1905.

THE TREATMENT OF RINGWORM OF THE SCALP BY THE X RAYS.

To the Editors of THE LANCET.

SIRS,—I have read with much interest Dr. H. G. Adamson's article on this subject in THE LANCET of June 24th and I should be glad if he would give us the benefit of his experience with regard to the liability to burn in different individuals. I have lately had three very instructive cases, all treated at the same time, with the same current, and the same tube. Case 1.—A lady, aged 96 years, with malignant ulceration had one exposure of 13 minutes. She was unable to come again but eight days after showed definite signs of a burn. Case 2.—A lady with lupus of the nose had seven exposures of 12 minutes. On the fifteenth day from the first exposure she showed definite signs of burning which increased for several days. Case 3.—A lady with a small rodent ulcer has had 12 exposures of 12 minutes and shows absolutely no signs of any burns. Will Dr. Adamson kindly say where Sabouraud's pastilles can be obtained?

I am, Sirs, yours faithfully,
WINWOOD SMITH.
Cockington, Torquay, June 26th, 1905.

DUST-BORNE TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—The epidemic of typhoid fever at Bridgend is of special interest from the fact that the medical officer of health attributes it to the blowing about of infected particles in dust. Can any of your readers refer me to other recorded instances of dust-borne typhoid outbreaks?

I am, Sirs, yours faithfully,
HERBERT JONES.
Hereford, June 13th, 1905.

THE NEW COUNTY HISTORY OF NORTHUMBERLAND.

To the Editors of THE LANCET.

SIRS,—On behalf of ourselves and a considerable number of other medical men assembled at a meeting called for the purpose of considering the following matter, we wish, if you will allow us, to bring it in your pages before our professional brethren in order to elicit as far as practicable their collective opinion about it—viz., whether it is correct ethics or otherwise for medical men to allow their names with personal histories or biographies and photographs, all furnished by themselves, to be published in a work now being brought out which purports to be a county history of Northumberland at the opening of this century, with contemporary biographies and which is advertised by its publishers as "A Romance of Commercial Enterprise and Business Ability"?

We may say, as throwing some light upon the methods adopted in bringing out this publication, that some of us have been given to understand by the agent of the publishers, when he called, that our names, &c., would only be admitted to its pages if we were willing to subscribe for a copy of it at £5 5s., although this, when mentioned to the publisher himself, who has come north to further the enterprise, has been stated by him not to be correct; however, the fact remains that when several of us as a test question asked his local agent whether our names, biographies, and photographs would be inserted if we did not subscribe for copies, we were told that it was purely a business transaction and that they would not be inserted on other conditions, with the result that the agent withdrew when this was not agreed to. We also have been told that the selection of those who are considered to be "men of standing" sufficient for this publication is made according to the advice of some "local man" who is therefore the arbiter to say who is eminent enough to have his personal biography and photograph admitted to the pages of this so-called "County History."

To the plain man this enterprise will, we think, appear to be only a form of self-advertisement for which many, if not all, would have to pay in the way above indicated in order to be included. We recognise, of course, that numerous eminent public men are included in these volumes (for other counties also have been dealt with) but as much of the history of such men is public property it is difficult to see how they could be kept out even if it were desirable, which we do not assert. We cannot for our part distinguish between the supplying of professional details by professional men in order that they may be published in a book of this kind and any other advertisement for which one would have to pay, if such a thing were not forbidden up to the present time by what we have always understood to be the canons that govern the conduct of all members of the learned professions of this country.

We are, Sirs, yours faithfully,
R. S. PEART, *Chairman.*
LACHLAN FRASER, Honorary Secretary.
North Shields, June 20th, 1905.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

To the Editors of THE LANCET.

SIRS,—Will you kindly extend to me the hospitality of your columns in order to notify all diplomates of the Edinburgh Colleges that a petition will shortly be sent round for signature praying for the addition of a Membership to the existing R.C.S. Ed. qualification. As the expense of the petition will necessarily be very heavy I should be glad to acknowledge any subscriptions sent by diplomates in favour of the movement.

I am, Sirs, yours faithfully,
DAVID WALSH,
Honorary Secretary of the Association of Medical Diplomates of Scotland.
18A, Hanover-street, London, W., June 27th, 1905.

WOOD *v.* BAILEY.

To the Editors of THE LANCET.

SIRS,—In your article on the above case published in THE LANCET of June 24th the following statement occurs:—

> It would, nevertheless, be satisfactory to the profession to hear from him [Dr. Cowper] that he had endeavoured to prevent a defence which he must have foreseen to be futile and that he had striven to enlighten Mr. Bailey with regard to the true nature of his position and his responsibilities.

In reply to this I may state that the first intimation I had that the above case was pending was when Mr. Bailey called on me a few days before the trial. I told him plainly that the defence was absurd and that he would certainly lose the case. I said to him: "If it were possible for you to win a case like this the practice of medicine would be impossible." I pointed out to him that we (medical men) were in the same position as other professional men and asked him if he had ever heard of a barrister being refused his fees because he had not conducted his case differently to what he had done. I told Mr. Bailey's solicitor the same thing and I further said that I declined voluntarily to go as a witness.

You state the plaintiff, Dr. Wood of Shanklin, &c. I may say Dr. Wood practises at Sandown, where the patient resides, whereas my partner and I practise in Shanklin. I may say that my partner (Dr. Hammond) gave Mr. Bailey's solicitor advice similar to that which I gave him.

I am, Sirs, yours faithfully,
JOHN COWPER.
Shanklin, June 28th, 1905.

CERTIFICATION UNDER THE LUNACY ACTS.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if you would kindly inform me whether, in the event of a club patient having to be sent as a pauper to an asylum, it is usual for the relieving officer to obtain the lunacy certificate from (*a*) the Poor-law medical officer or from (*b*) the medical man in attendance. I am, Sirs, yours faithfully,

June 15th, 1905. A. B. C.

⁂ To determine the exact procedure required in order to get an insane person who, by reason of his mental infirmity, has become chargeable to his parish or union into an asylum is a perennial source of trouble to medical men. This is a natural consequence of that difficulty in interpreting the provisions of the Lunacy Acts which results from the ambiguity of the language of those statutes. We have frequently had occasion to deal with this topic, but the above letter shows that there are still rough places to be made smooth. Our correspondent asks whether, in the event of a club patient having to be sent as a pauper to an asylum, it is usual for the relieving officer to obtain the necessary medical certificate from the Poor-law medical officer or from the medical man in attendance. The question indicates some misapprehension of the relieving officer's position. It is not the business of this officer to obtain a certificate at all. His duty under the Act of 1890, as laid down in Section 14, subsection (2), consists in giving notice to a justice having jurisdiction that there is an alleged lunatic to be dealt with. Section 16 directs the *justice* to call in a medical practitioner and no restriction is placed upon the choice which the justice may make except that Section 32 prohibits the employment of an interested person. It is, however, quite a common thing for boards of guardians to arrogate to themselves the selection of a medical man. Acting through their relieving officer they require their own medical officer to certify and make the fees which they have to pay for the certificates a part, and sometimes a considerable part, of his salary. Justices often, it would appear, through ignorance of the extent of their own powers, acquiesce in the arrangement. There is no doubt that this course is productive of much annoyance to the general practitioner, especially in the case of club patients, who are not ordinarily sources of much profit to their medical attendants, but it must be remembered that the Poor-law medical officer has also some right to be considered and that any departure from the customary routine which a justice might see fit to make would involve an already badly paid official in pecuniary loss for which the Lunacy Acts provide no compensation. —ED. L.

MEDICAL CERTIFICATES IN RESPECT OF SCHOOL ATTENDANCE.

To the Editors of THE LANCET.

SIRS,—The education committee of the Surrey county council last year introduced tentatively a scheme for the certification of absentee school children by the medical officers of health of a few of the Surrey districts. A fee of 5*s*. was paid for a visit to the home of the child. Although in some of the districts this might involve a journey of eight miles some of the members of the committee considered the fee excessive and the scheme was abandoned. The school attendance committee of the petty sessional division of Guildford then approached some of the medical men practising in one part of its district with a view to their examining children at their surgeries and giving the necessary certificate for a fee of 1*s*., or visiting the children at their homes for a fee of 2*s*. The offer was accepted by two practitioners, although the district in question comprises some 21 square miles! The commendable action of the Sevenoaks division of the British Medical Association mentioned by Dr. O. D. Marriott in THE LANC of June 24th might with advantage be extended to th district. I am, Sirs, yours faithfully,

X.

THE HOUSE OF LORDS COMMITTEE O THE SANDGATE "SANATORIUMS" NUISANCE.

(BY OUR SPECIAL SANITARY COMMISSIONER.)

THE minutes of proceedings taken before the Select Co mittee of the House of Lords on the Sandgate Urb District Council (Sanitary Powers) Bill go far to confi what has been said in these columns concerning the p tended out-door treatment of patients suffering from tub culosis at the homes of the late Mr. J. J. Jones of Sandga The more sensational features of the case were, it is tr somewhat toned down. The fact that the author of t whole grievance is dead and that his successors seem to ha endeavoured to effect improvements suffices to explain t more considerate attitude adopted. There was a very natu desire to avoid as far as possible hurting the feelings the youthful and comparatively irresponsible successor the management. Much trouble has recently befallen t family. The late Mr. J. J. Jones had somehow succeed in gaining possession of 19 properties at Sandgate and so 30 houses. The son who helped him to manage this proper died suddenly and in dramatic circumstances. Shor afterwards Mr. J. J. Jones fell ill and died in March, 19 Another son, Mr. P. H. Jones, had been sent directly fr school to Paris and had been in business there for sev years. Suddenly he was called upon to give up Paris business and to take in hand the management of t homes and properties at Sandgate. This Mr. Jones, thou only 26 years old, seems to have acquired some busin capacity as an administrator, but he could not have a technical knowledge as to sanatoriums or any perso knowledge of the Sandgate business. He does seem, ho ever, to have realised that this business was not carried on a very correct manner. Notably, he felt that the medic control was not sufficient and also that it was folly pretend that the treatment was similar to that given Nordrach, Davos, and Leysin. He consequently destroy 10,000 circulars which made this assertion and which father had printed. In these circumstances there was general desire to deal gently with Mr. Jones, jun. Nev theless, the main principles at issue remain unaltered a attempted reforms made to-day are no guarantee for t future. Such reforms may be due to an honourable des to remove grievances or merely to fear engendered the actual and very general outcry. In either case a char of management or a change of disposition may produ other alterations and there is nothing to prevent matt from becoming as bad as, or worse than, they were in t past.

As an example of such instability the late Mr. J. J. Jor wrote to me on July 21st, 1903, giving a list of five hou containing 126 beds which, he stated, were "used strictly a exclusively for phthisical patients." He also mention three other houses with 80 beds for children and co valescents from infirmaries. That these figures might altered and probably increased is shown by the fact th Mr. Jones further remarks in this letter that "the numb stated are as accurate as we can give you at the prese time," and adds: "We calculate we can receive af the end of this week when the transfers have been made a the enlarged accommodation in use, about 23 more patient Thus it seems as if the late Mr. Jones contemplated receivi 149 tuberculous patients. At that time apparently it w the policy to exaggerate rather than to minimise the numb of cases of tuberculosis taken into the homes at Sandga The late Mr. Jones even succeeded in convincing the medi officer of health, Dr. C. E. Perry, that he had received his homes during the year 1903 no less than 880 tuberculo patients. Now Mr. Jones, jun., appears before the Hou of Lords Committee and states that there are only 1 beds available for tuberculous cases and that he has look through his father's books and can only find trace of 5 tuberculous patients as having been received in the hom during the year 1903. The number of deaths, however, is not challenged and the fact that 43 patients died out of 518 may be considered as creating a greater danger for the surrounding population than if there had been 43 deaths among 880 patients. It shows that the patients were in a more advanced stage of the disease and therefore less suited to the sanatorium methods of treatment; at all events measures were taken to check this state of affairs, letters being written to boards of guardians complaining as to the condition of the patients whom they sent to Sandgate.

Of the various criticisms made in the original indictment published in these columns,[1] that which seems to have been most taken to heart was the denunciation of the fact that there was no medical control. Prospectuses were so worded as to infer that there was responsible medical supervision; but Dr. W. L. Chubb, whose name was mentioned in this connexion, explained to me that though he was called in to give advice to patients he was no more responsible for the condition of the homes than he would be for the drainage or the diet of an ordinary hotel where one of the visitors might fall ill and send for him. Indeed, the position was such that ultimately, and to put an end to all misunderstanding, Dr. Chubb refused to have anything more to do with the late Mr. J. J. Jones and his patients. An agreement was then drawn up, dated September, 1903, with Mr. A. J. Gore, which was produced in evidence to show that now, at least, the homes were under proper medical control. The post given to Mr. Gore is described in that document as that "of consulting and acting physician and doctor to the said Sandgate Sanatoria and Convalescent Homes aforesaid." The document specifies that "the said medical superintendent shall have the full control of all matters relating to, or in connexion with," and "shall be solely responsible for the general comfort and welfare of the said patients and for all medical attendance, prescriptions, and dietary instructions." If the matrons and nurses do not carry out the instructions given they can be dismissed by the medical superintendent. So it would seem as if something like medical control had at last been established and for this Mr. Gore was to receive a retaining fee of £104 a year and certain other fees which brought up the total to £287 last year. But it appeared in evidence that this deed was drawn up on behalf of Mr. J. J. Jones, who is dead, by his son, Mr. F. T. B. Jones, who also is dead, and is now carried out by Mr. P. H. Jones who has no legal right whatsoever in the matter. There are five members of the family who claim the estate of the late Mr. J. J. Jones. They propose to draw up a deed of partnership and they propose to appoint Mr. P. H. Jones to manage the estate, but as yet they have done nothing of the sort. Finally, instead of an estate representing a valuable property they find that there are £10,000 of debts. Then, again, even if all prospered and the agreement mentioned was renewed in a proper and legal manner it contains a clause by which it can be revoked after a three months' notice. Thus it will be seen that there is no guarantee whatsoever that proper medical control will be permanently established. Nor can it be said that the appointment of a medical man in control is a sufficient guarantee. That medical man remains the servant of an employer to whom business and not the treatment of disease is the primary object. If the medical attendant is a poor man and receives from this one source about £300 a year it puts him in a position of great dependence. It is not fair to expect anyone to be ready to give up his means of existence because his instructions are not properly carried out. It is not reasonable to expect that the medical attendant would endeavour to carry out methods of treatment involving such expense as would be almost certain to entail his dismissal. On the other side, the manager of a commercial concern whose sole aim is financial success would endeavour to find a medical man ready to assume the responsibility of control, while at the same time making that control as little expensive and irksome as possible. Evidently such matters should not be subordinated to the financial interests of either the employer or the employed. Therefore the Bill will be useful if, as proposed, it lays down a set of rules and regulations which must be carried out in sanatoriums and this independently of the opinions or desires of the owners of such establishments or of the medical attendants appointed to treat the patients. Indeed, it must also be borne in mind that outdoor treatment and sanatoriums for tuberculous patients have brought into existence a comparatively new technique that has been developed within the last few years. It therefore does not follow that any and every qualified medical practitioner knows all about this new subject.

The evidence given by some of the medical witnesses before the House of Lords Committee showed that technical knowledge of sanatoriums is not general. For instance, Mr. Gore himself stated in evidence that he had had no experience of public institutions. Some years ago and by courtesy he had attended the practice of the out-patients' department of the City of London Hospital for Diseases of the Chest, Victoria Park, but this, of course, has nothing to do with sanatoriums. In regard to the technique of sanatoriums the general rule is that there should be a classification of cases and according to Dr. Walters's and Dr. Ransome's works there should be one medical attendant for every 40 patients. The temperature of these patients should be taken three times a day and they should be carefully watched at meals. At the Jones's homes there are actually 215 beds and there is no law to prevent tuberculous patients being placed in all these beds, and in that event there is no law to compel the employment of a proportionate number of medical attendants. It was stated in evidence that it was doubtful whether more than 100 beds were occupied at any one time by tuberculous patients. Still, even this is a good deal in excess of the 40 patients which it is supposed are enough for one medical attendant. Then, as these patients are, or were, lodged in five different houses the one medical attendant cannot watch over all the meals and see that each patient gets exactly what he needs. As a matter of fact, it is, of course, preposterous to suppose that constant and personal surveillance over the meals can be exercised in such circumstances. Mr. Gore said in his evidence that he had seen the patients at all their meals and doubtless he has done so once or twice, but the conditions of the patients change from day to day and one of the advantages of a sanatorium is that day by day and hour by hour the patients are being watched by highly qualified medical men. Mr. Gore, however, has a private practice outside Sandgate, he does not even live at Sandgate; and if he did he could not reside in five different houses at one and the same time; so it results that there is no resident physician whatsoever. Yet, on the other hand, there are 100 or so patients and these are not cases in the incipient stage. The patients had in many instances reached so advanced and dangerous a stage that Mr. Gore related, in his evidence, how he had written to the boards of guardians protesting against such desperate cases being sent to Sandgate. Nevertheless, in 1904 there were 24 deaths out of a total of 441 patients who spent some part of the year at Sandgate. To be single-handed with so many patients is not in keeping with the practice of well-regulated sanatoriums. On the other hand, it is difficult to see how a commercial enterprise of this description can be made to pay if a sufficient staff of medical officers is engaged.

The financial problem becomes all the more difficult in the face of the strange evidence of Mr. Jones, jun. He declared that he had given up all intention of taking in paying patients. The late Mr. Jones declared to me that he had spent some £1500 to refurnish, to decorate, and to convert Farleigh House into a sanatorium for the reception of what he qualified as first-class paying patients. These were to pay 35*s.* a week, or 45*s.* if they had a private room. Then there were also second-class patients who paid 25*s.* a week, or 33*s.* if they had a private bedroom. Finally, there were the patients from the workhouse infirmaries and for them the board of guardians paid at the rate of £1 1*s.* per week. The 34 beds in Farleigh House, the 15 beds in Lymington House, and the 14 beds in Ontario House were all to be occupied by paying patients and the late Mr. Jones boasted that more than 2000 paying patients had availed themselves of the advantages which he offered. Now we are told that the result of this business is £10,000 of debts. Then we are told that with two exceptions all the paying patients are gone, that no effort is being made to attract others, and that the business is now limited exclusively to pauper patients who occupy even Farleigh House in spite of the £1500 recently spent in luxurious furniture and decoration. It is perhaps not surprising that paying patients should have become scarce, but the extraordinary thing is that the late Mr. Jones with his hundreds of paying patients is said to have made debts to the amount of £10,000, while the present Mr. Jones though but new to the business and dependent solely on pauper patients is actually making such profits that he hopes in time to pay off his father's debts. Thus it is stated before a committee of the House of Lords that paupers for whom not more than 116 beds are now available receive proper medical attendance, sufficient milk and food of good quality, and healthy house accommodation, with no overcrowding, all for one guinea a week; and further, that out of this one guinea per head per week the margin of profit is so large that hopes are entertained of paying off an enormous debt of £10,000. *Does this seem rational?* And if such profits accrue what will be the fate of the patients? Is it not time that the patients should be protected by a law establishing rules for the management of sanatoriums?

---

[1] THE LANCET, August 22nd, 1903, p. 565.

That is what the Bill *proposes*. Such establishments must have a licence. The licence will not be given unless rules and regulations approved by the Local Government Board are applied, and therefore the owners of unsuitable private dwellings in which tuberculous patients are huddled together as if they were tenants of a common lodging-house will no longer be allowed to receive such cases. So far so good, but the Lords Committee insisted on adding a clause giving a double compensation. If a licence is refused to the owner of a house for tuberculous patients and he is not allowed to take in any more patients then he is to be compensated for the cost of structural alteration incurred in putting his house to some other purpose. As a case in point the removal of the cubicles from Grosvenor House, where the paupers are partitioned off from each other, was mentioned. Secondly, and this is a much more serious matter, the owner is to be compensated for disturbance in his business for, as it were, the loss of the "goodwill" of the business.

Before the sanitary and medical aspects of this particular Sandgate business were taken up in these columns *Truth* had been following for some ten years the career of the late J. J. Jones, denouncing his religious begging-letter impostures and demanding some control over the donations which he obtained from charitably disposed persons. By methods thus publicly challenged a nuisance has been created which has seriously injured the prosperity of Sandgate and depreciated the value of property in that town. But it is not the Jones family who are called upon to pay compensation to the town of Sandgate for the unquestioned harm they have done; it is, on the contrary, the ratepayers of Sandgate who have to compensate the Jones family if they try to do away with this mischief. This is what *Truth* qualifies as "a monstrous state of things," and it adds:—

> The Jones family have created and carried on this business under conditions which the law ought never to have tolerated. Sandgate has thereby been heavily damaged as a seaside resort, yet the noble lords constituting this Select Committee now actually insist that the unfortunate ratepayers, if they seek to interfere with the cause of the mischief shall pay compensation to the parties responsible for it' The decision virtually recognises a vested interest in a public nuisance.

The ratepayers and district council of Sandgate, instead of being mulcted in this manner, merit the gratitude and some sort of substantial support and recognition on the part of the entire United Kingdom. Great Britain in respect to sanatoriums for the treatment of tuberculosis and to laws regulating the same is much behind several continental nations. The local authorities at Sandgate at their own risk and cost have taken the first step towards obtaining for the country some sort of legislation on the subject. Of course, their Bill only affects their district but it is obvious that it will serve as an object lesson and a precedent for the rest of the country. And at present what is the lesson? First, that it is advantageous to join some religious body and under the guise of charity to obtain possession of house property and land. Then the next step is to create a nuisance on that property and to persist in the nuisance till the neighbours are compelled at any cost to abolish the nuisance. In that event there will be compensation forthcoming and thus ample means will be provided to begin the whole process over again elsewhere. If the younger generation of the Jones family had the enterprise and energy of the late J. J. Jones they would already be purchasing property at Hythe or some other similar place so as to transfer their business from Sandgate and wait there till another Bill, with the complacent aid of the Lords, gave them another claim for further compensation.

In spite of the decision of the Lords Select Committee it is difficult to see where the claim for compensation comes in. No one proposes to confiscate any of the property belonging to the Jones family. In certain towns, notably in Ireland, the inhabitants keep pigs in their private dwellings. In England poultry is kept. Then these places grow in size and rules are enacted to the effect that pigs and poultry must not be kept in the crowded and central parts of such towns. Is compensation paid to the people who have created a nuisance with their pigs and poultry? Then again factories or mills are started. In the course of time it is found that many accidents occur and laws and regulations are enacted stipulating that machinery shall be railed off or protected by netting, &c., so as to prevent accidents. In some cases the machines were so awkwardly placed that this could not be done, so it was necessary to stop working the machines or to remove them elsewhere. In other cases expensive apparatus for better ventilation or the carrying off of dust had to be introduced. Was compensation claimed and given? The Jones family have created a new industry at Sandgate. This industry is proved to be a danger and a nuisance. The demand is that their dangerous machinery shall be fenced off; in other words, that the houses in which, for industrial or money-making purposes, they herd together tuberculous patients shall be separated from the rest of the community by a large open space. Further, the demand is that they shall not profess to give outdoor treatment when they have no outdoor space at their disposal, that they shall be made by law to act up to their professions and promises, and if they cannot do so then that they must give up the business. Where in all this lies the claim for compensation? It will be a very dangerous thing if a precedent is established giving right of compensation to all who succeed in creating some novel kind of nuisance which was not foreseen and specified by laws enacted previously to the invention or discovery of the new process giving rise to the novel means of endangering public security. What is required at Sandgate does not differ from that which already exists on the continent and it is a serious matter if we cannot bring ourselves up to the continental level without having to pay compensation to the authors of nuisances. It is a pity that more evidence was not given before the Lords Select Committee as to what is being done on the continent; the members of that committee might then have been more anxious to facilitate the acquisition in England of laws, regulations, and methods that would compare more worthily with those which exist abroad.

THE fifth degree congregation will be held in the large lecture theatre of the Birmingham and Midland Institute on Saturday, July 8th, at noon. The vice-chancellor will confer degrees and in the afternoon the pro-vice-chancellor will give a garden party —The council has decided to invite Sir Archibald Geikie to deliver the Huxley lecture in 1906.—The dean of the Faculty of Medicine (Professor H. G. Barling) has presented to the University a portrait in oils of Dr. John Tomlinson Ingleby, in memory of whom the Ingleby lectures and scholarships were established by his son, the Rev. Charles Ingleby.

Presentation to Dr. E. Rickards.

The retirement of Dr Rickards from the office of honorary physician to the General Hospital has been considered by his friends and colleagues a suitable occasion to testify to the regard in which he is held and to the gratitude which they feel for his long and valued services to the charity. The presentation took the form of a grandfather's clock in carved oak and brass finishings and an illuminated address containing a record of the resolution passed by the board of management at the time of his resignation. The address was in the twelfth century style and into the various borders were introduced water-colour sketches of the old and new General Hospitals. The volume was bound in dark green morocco. An engraving of Dr. Rickards was also presented to the hospital accompanied with the request that it might be hung in the Medical Common Room as a permanent record of his faithful and valuble services. Mrs. Rickards was the recipient of a diamond necklace and a copy of the engraved portrait of her husband.

"Reformatory" Conference in Birmingham.

The triennial conference of the Reformatory and Refuge solely on pauper patients is actually making such profits that he hopes in time to pay off his father's debts. Thus it is stated before a committee of the House of Lords that paupers for whom not more than 116 beds are now available receive proper medical attendance, sufficient milk and food of good quality, and healthy house accommodation, with no overcrowding, all for one guinea a week; and further, that out of this one guinea per head per week the margin of profit is so large that hopes are entertained of paying off an enormous debt of £10,000. Does this seem rational? And if such profits accrue what will be the fate of the patients? Is it not time that the patients should be protected by a law establishing rules for the management of sanatoriums?

That is what the Bill proposes. Such establishments must have a licence. The licence will not be given unless rules and regulations approved by the Local Government Board are applied, and therefore the owners of unsuitable private dwellings in which tuberculous patients are huddled together as if they were tenants of a common lodging-house will no longer be allowed to receive such cases. "Reformatory" Conference in Birmingham.

The triennial conference of the Reformatory and Refuge afterwards the new premises in Rye Hill were declared open by Lord Armstrong. The house which has been acquired for the hospital has been for years the residence of successive vicars of Newcastle. The accommodation includes two wards, one for each sex, with five beds in each, as well as spacious consulting and waiting rooms and an operating theatre. Last year 2364 new patients were treated and of these 1717 contributed £373 to the funds, a fact which has been favourably commented upon more than once by the supporters of the institution. There is at present a deficiency of £2400 on the new premises fund account. only £600 having been subscribed so far. Professor Sir George Hare Philipson and Professor Frederick Page were elected honorary consulting physician and surgeon respectively and Dr. R. S. Hindmarch was appointed honorary anæsthetist.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Medical Fees under the Midwives Act.

IT has long been felt that some provision should have been made in the Midwives Act for the payment of a medical man who is called in by a midwife in those cases where she herself is not permitted to act alone. The Cardiff Medical Society and the Cardiff division of the British Medical Association have both discussed the question and the opinion has been generally expressed that the supervising authority should pay a fee to the practitioner who is called in upon such occasions. In Cardiff the supervising authority is the health committee of the corporation and the medical officer of health (Dr. E. Walford) is intrusted with the administration of the Act. After conferring with the medical men in the town the authority has decided to recommend to the corporation that a fee of one guinea should be paid to a medical practitioner called in by a midwife if he is unable to obtain payment from the patient or from the board of guardians. The payment is only to be made, however, in cases of flooding, convulsions, and rupture of the uterus.

The Medical Officer of Health of Chipping Sodbury.

The circumstances attending the secession of Chipping Sodbury from the combination of districts for which Dr. F. T. Bond has been medical officer of health during the past 32 years have already been referred to in THE LANCET. The Chipping Sodbury rural district council having elected as medical officer of health a local practitioner it was necessary to obtain the sanction of the Local Government Board to his appointment in order to obtain from the county council funds a moiety of his salary. The Board withheld this sanction until a meeting had been held of representatives of the councils constituting the combination. This meeting was held on June 19th, when delegates from all the constituent councils attended with the exception of the Chipping Sodbury council, a formal resolution refusing to be represented having been passed by that council Two resolutions were passed at the delegates' meeting, one regretting that the Chipping Sodbury council contemplated withdrawing from the combination and urging in the most friendly spirit a reconsideration of the matter. The other resolution expressed the opinion that no evidence had been submitted to justify any alteration in the arrangements hitherto existing for the maintenance of the combination and that it would be to the advantage of the districts forming the combination that it should be continued on the same conditions as heretofore. The Local Government Board has now, therefore, a formal representation as required by Section 286 of the Public Health Act and can make an order for the compulsory combination of the districts concerned, but it is to be hoped that wiser counsels will prevail with the members of the Chipping Sodbury council and that they will follow the advice of their neighbours and reconsider the matter.

Typhoid Fever at Bridgend.

During the week ending June 17th there were 19 cases of typhoid fever notified in Bridgend and in the previous week there were 13, making a total of 65 cases since the beginning of the outbreak in the third week of May. Four of the cases have ended fatally. The district council has asked the Local Government Board to send a medical inspector to investigate the cause of the epidemic.

The Sale of a Medical Practice in Bideford.

At the Newcastle bankruptcy court on June 22nd his honour Judge Greenwell granted an application made by Dr. Alexander Lane of Newcastle for his discharge from bankruptcy. The applicant became a bankrupt as the result of an action brought against him at the Devon assizes last February by Mr. Ellis Pearson of Bideford, which case was reported in THE LANCET of Feb. 18th, p. 465. His honour remarked that he could not help thinking that the legal action over the sale of the practice should never have been brought and that the verdict was wrong, and as that action had brought about the debtor's bankruptcy and as the petitioning creditor (Mr. Pearson) was the person who was responsible for the proceedings, he thought he was justified in saying that the bankruptcy was brought about in the terms of the section by a misfortune which it was not in the power of the debtor to avoid and therefore he gave him his discharge at once.

June 26th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University Reform.

FOR some time a scheme has been on foot to institute in the Scottish universities a three-term session instead of the present winter and summer sessions. During the early part of last century the old arrangement of winter and summer sessions was no doubt an advantage to the student. All courses of lectures which were essential to graduation could be taken out during the winter, while the summer session was devoted more especially to tutorial classes and more advanced lectures intended for those who were aiming at an "honours" degree. The advantage of this arrangement was considerable when one recollects that the average Scotch student was by no means wealthy and that it was in many cases only with the greatest difficulty that he could raise the money necessary for his fees. Under the old arrangement he was free during the summer months and it was the common practice for students, by teaching or otherwise, to make enough money during these months to carry them through the ensuing winter months at the University. It was only by resorting to this plan that men like William Cullen and William Hunter were enabled to complete their education. But nowadays the condition of affairs is completely altered. So many subjects need to be taught that the summer as well as the winter months are required by the university teachers to enable them to cover all the work. On the other hand, the student of the present day can better afford to pay the fees and even if he cannot assistance can be obtained from the Carnegie Fund. The Scottish universities have determined that the time has come to make some alteration and a meeting of delegates from the four universities recently took place in Glasgow to consider the question of the proposed three-term session in place of the present winter and summer sessions. The meeting was held in private but it is understood that the opinion was decidedly in favour of the proposed change. Before the alterations can be carried out a good many difficulties will have to be overcome owing to the cumbrous machinery which needs to be set in motion before any such reform can be effected, but no doubt the matter will be pushed forward as rapidly as possible. Students of the arts curriculum will probably benefit most by the new arrangement. In medicine it will make but little practical difference, for, owing to the multiplication of subjects and the necessity for holding practical and laboratory courses, the summer months have already come to be considered by the student as important a part of the university year as the winter months.

Tramcar Life-guards.

The tramways committee in Glasgow has been experimenting with various kinds of life-guards with a view to find if any improvements can be made on the one which is attached to the cars at present. Extensive experiments were made with the guard which has been adopted in Dundee on the strong recommendation of the Board of Trade. The committee came to the conclusion that the one at present in use in Glasgow is the best and by corresponding with the various municipalities it has ascertained that this same guard has been fitted on to 90 per cent. of the cars at and to provide recesses in connexion with the library. Increased space will be provided for storing books and also for a pathological room and patients' waiting rooms. The resident librarian's house which adjoins will be absorbed in the building, thereby allowing for a large increase of space which is necessary for the comfort of members.

The Liverpool Royal Infirmary.

Mr. Charles Thurstan Holland has been appointed medical officer in charge of the electrical department of the Royal Infirmary. Mr. Thurstan Holland is the president of the Röntgen Society, London.

June 27th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Non-notification of Small-pox at Accrington.

A WEEK or two ago it was mentioned that proceedings were to be taken by the Accrington corporation against a medical man and an ex-town councillor for the non-notification of small-pox, from which disease children of the latter were suffering. At first one of the cases was mistaken for chicken-pox but "further developments of the disorder" led to communication with the medical officer of the corporation by telephone—which, it is stated, is not a legal notification—asking him to call at the house and to see the patients. As a result of this all the affected members of the family were taken to the hospital and the others were isolated. The health committee had the medical man before it and passed a resolution that the head of the family—not of the medical man's family—should be admonished for "regrettable neglect." Next, when the town council met an antivaccinationist member asserted that the patients taken to the small-pox hospital had not got small-pox. To uphold the authority of the council and its medical officer it was determined to prosecute the medical man and the others implicated and to sue the head of the family for the recovery of the cost of treatment at the hospital. However, "all's well that ends well." The medical man has written to the town clerk a letter for submission to the council admitting that he must have made a mistake, which has been accepted as a satisfactory vindication of the authority of the medical officer and of the action of the health committee, and all the contemplated prosecutions are to be dropped, "it being considered that sufficient publicity has been given to the requirements of the statute." Best of all, the borough is now said to be free from small-pox. Preston, however, which only got rid of the disease a few months since, is now again threatened with a serious outbreak, 16 cases being in hospital a fortnight ago. A further increase has taken place since then, making the number of recent cases about 34, and on June 23rd 21 cases—five men and 16 women—were still in hospital. The medical officer of health says there is no reason to attribute this fresh outbreak to certain "show" people, as had been rumoured. He adds, however, the somewhat uncomfortable remark that it is very likely due in a great measure "to the contact of the healthy with the infected in streets, railway carriages, and elsewhere during the holiday season." There is no doubt that the early diagnosis of small-pox from chicken-pox is sometimes far from easy but the "shottiness" of the former eruption rarely fails to afford help. Still mistakes occur and at Todmorden a tradesman threatens an action for compensation because his daughter has been taken to hospital as suffering from small-pox, while he contends that she only had a serious attack of chicken-pox.

Births and Deaths in Cheshire.

In his annual report to the Cheshire county council Mr. F. Vacher gives some interesting facts. Of the municipal boroughs Macclesfield had the lowest birth rate (22·6 per 1000) and the highest death-rate (20·4 per 1000), while Crewe, which is the largest municipal borough in the county, had the highest birth-rate (30·9 per 1000) and the lowest death-rate (14·6 per 1000). In the other urban districts Hoole, near Chester, had the highest birth-rate (38·6 per 1000), while its death-rate was 20 per 1000. The causes of these differences are not self-evident. Crewe is a busy town of railway workers, on a flat plain, pretty well provided with clay. Macclesfield is hilly and situated where the plain rises to the almost mountainous division between Cheshire and Derbyshire, while Hoole again is on the plain and has a good proportion of well-to-do people. But the statisticians say that the birth-rate among this class of people tends to fall. The population of the county is now estimated at 609,316, the county area being 644,180 acres, giving a little over an acre to each person.

June 27th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

New Appointments at the Royal Infirmary, Newcastle-upon-Tyne.

UP to the present time the assistants in the special departments of the Royal Infirmary, Newcastle-upon-Tyne, have either been senior students or qualified men who were willing to devote their time to the work without official recognition. It has now been decided by the infirmary committee that these appointments shall only be held by fully qualified men who are engaged in the practice of the specialty of the department with which they are associated. For some years the committee has unofficially recognised the *locus standi* of the gentlemen who have been assisting in the throat and skin departments by allowing their names to appear in the annual reports of the two departments as having given valuable assistance. This has placed certain members of the committee in rather an awkward position with regard to the throat department where there were several candidates for an appointment, because they naturally felt that they were bound to support the gentleman who for so long had been unofficially connected with the department. This really made little difference in the present instance, for Dr. S. S. Whillis, who secured the position, was in any case a very popular candidate, but it shows the difficulty in which a committee may be placed by unofficially recognising the services of gentlemen who are allowed to work in any department of a hospital without being properly appointed. Dr. D. W. Patterson was appointed assistant to the skin department, there being no opposition.

Medical Association for Haltwhistle.

This is a movement which is just in its infancy at Haltwhistle for it was only on June 17th that steps were taken to form a committee to discuss the rules and regulations and accordingly a president, treasurer, and secretary were appointed.

Memorial to the late Dr. James Murphy.

A movement has been already started in Sunderland to raise a sum of money to provide a memorial to the late Dr. James Murphy. It is suggested that an ambulance should be procured for the town and that any surplus should be used for some form of memorial more conspicuous. A vacancy which his death has caused in the surgical staff of the Sunderland Infirmary has been filled by the appointment of Dr. William Robinson. For several years Dr. Robinson has been physician to the infirmary and by his transference to the surgical side a vacancy has been created for which there are already several candidates in the field.

The Prevention of Consumption.

The annual meeting of the local branch of the Association for the Prevention of Consumption and other Forms of Tuberculosis was held on June 19th in the College of Medicine Newcastle-upon-Tyne. Lord Armstrong presided and there was a fairly representative gathering. The secretary (Dr O. W. Ogden) was able to state that the erection of the sanatorium at Barrasford-on-Tyne was progressing steadily and if only the necessary funds were forthcoming the building, with accommodation for 50 patients, would be ready by the end of the year. To make this possible it would be necessary to raise £7000 without delay. After the business part of the meeting Sir Isambard Owen delivered an address in the course of which he pointed out that the question of establishing a sanatorium for consumption was not a matter of charity but a matter of sound public economy. On the motion of the chairman the name of Sir Isambard Owen was added to the list of vice-presidents.

Newcastle Throat and Ear Hospital.

The twenty-seventh annual meeting of the supporters of this hospital was held on June 19th and immediately

PARIS:

(FROM OUR OWN CORRESPONDENT.)

Abolition of the Internat en Pharmacie.

THE general council of the Seine has decided to pension f at an early date the senior (*doyen*) *pharmacien en chef* of e lunatic asylums. The vacancy thus created will not be lled and the event betokens an impending reform in e pharmaceutical department of the hospitals, a reform hich will in various ways effect a considerable aggregate aving. In a new asylum which the prefectoral administration, has in hand just now there will be neither *harmacien en chef* nor *interne en pharmacie* but the work of dispensing medicine will be done by assistants under he immediate control of a pharmaceutical chemist in the eighbourhood of the institution. If this experiment proves atisfactory the system will probably be extended to all the departmental lunatic asylums. The director of the Assistance Publique seems to be about to take a similar course, as may be inferred from the recent abolition of the position of *interne en pharmacie* in the hospitals of Brévannes, of Berck, and of Issy-les-Moulinaux.

Treatment of Pityriasis Versicolor.

At a meeting of the Therapeutical Society held on June 14th M. Gallois mentioned that painting a very extensive eruption of pityriasis versicolor with tincture of iodine might cause symptoms of iodism. Oxygenated water, on the other hand, presented a variety of advantages for this purpose. In addition to being a mild microbicide and harmless in other respects it was capable of dissolving albumin so that it might be expected to cleanse the skin and promptly to destroy the microsporon. M. Gallois has treated several patients in this way and always with success.

The Eyesight of Cyclists and Motorists.

At a meeting of the Academy of Medicine held on June 13th M. Chauvel read a report on a work by M. Mirovitch, entitled "Some Considerations on the Impairments of Vision due to Cycling and Motoring and on Methods of Remedying them." According to M. Mirovitch, the injurious influences in question were, especially in cyclists who maintain a high speed, the abnormal position of the head and the straining of the eyeballs in the effort to obtain distant vision. The action of the compression exercised by the air on the visual organs was less evident. The whole body was injuriously affected in cases of excessive speed, for the heart, the lungs, and the brain suffered as well as the eyes. M. Mirovitch recommended that the eyes should be protected by means of spectacles which permittted the circulation of air. These appliances seemed, however, to be too heavy for the use of cyclists and to be hardly available except for the drivers of motor-cars.

Sea Water in the Treatment of Tuberculosis.

M. René Quinton showed last year, as the result of a long investigation, that sea water ought to be considered as the true normal physiological medium for living creatures. It was in sea water that the most elementary of them were developed in the origin of species; it was also in a special manner the cradle of life on our earth, and throughout the complicated succession of living forms in evolution it has remained the nutrient fluid perpetually available. At a meeting of the Academy of Medicine held on June 6th M. Quinton, proceeding to consider some practical applications of his views, said that he had made a trial of sea water in the treatment of some pathological conditions characterised by alterations in the chemistry of the tissues, and that, assisted by M. Simon, he had commenced with tuberculosis. They first rendered sea water isotonic by diluting it with pure water until its saline component fell to 7 per 1000, the only proportion in which the fluid when brought into contact with the tissues of the human body did not cause changes in them. They then sterilised the fluid in the cold and injected from 50 to 300 cubic centimetres under the skin every three or four days. This treatment was employed for 18 tuberculous patients and showed unquestionable tonic properties from the very first. The patients gained weight steadily at an average rate of 27 grammes per day. Of the 18 cases, three who were treated at too advanced a stage were not materially benefited, but the remaining 15 were greatly improved, both in their general condition and also as regards the special lesions, whether in the lungs or the glands. The expectoration diminished and the bacilli in it were reduced in number.

Venereal Diseases.

The Director of the Assistance Publique has just taken a step which is worthy of notice. By means of posters distributed throughout Paris he has made it known to the populace that gratuitous advice with regard to the treatment of venereal diseases will be given at certain definite hours during the morning or the afternoon at 21 dispensaries. It is to be hoped that the municipal council will shortly arrange for evening consultations for the sake of those who cannot get away from their work during the day.

June 28th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Weather.

"SUMMER set in with its wonted severity," wrote Horace Walpole of Scotland, where, according to compatriot admission, "there is no climate but only weather." Is Italy tending to be a candidate for such sinister meteorological distinction? One might be pardoned for entertaining the misgiving if the experience of the last six months is to be repeated year by year. "Within the memory of the oldest inhabitant" (who, in spite of Mark Tapley, sometimes remembers something) such a winter as the last was never known, either for intensity or duration. During January and February the central provinces might have been a landslip from Siberia, and Florence, with the Arno frozen between the Ponte Vecchio and the Ponte Trinità, might as well have called herself Tobolsk. In the sunny, subtropical south we were little better off, looking out at Taormina, for instance, on steady snowfall, while (aggravating thought!) we read in the English papers that Brighton and Hastings were basking in delicious warmth. Spring brought little change for the better and we passed from the "chilled shot" of Boreas to the drenching hose of Jupiter Pluvius, till the customary stampede from Rome or Florence to the Lago di Como or Maggiore was arrested by the fact that the "Lakes" had met the stampeders more than half-way. Italy, indeed, must (meteorologically speaking) be on her better behaviour if she is to retain her character for azure skies and genial warmth and to attract to her cities and her seaboard that enriching flood of "forestieri" which is, to her shrivelled "circulation" what the rising of the Nile is to parched Lower Egypt. Even as I write, at the latter third of June, there is a steady rainfall, and not only is "Our Lady of Flowers" in an exceptionally lacrymose mood, but from every province, particularly in the Alta Italia and the Romagna, comes news of destructive hailstorms and persistent downpour with overflowing streams and battered vineyards, involving agricultural and winegrowing interests alike in something little short of ruin.

National Hygienic Competition.

In one of the masterly digests which the late Sir James Coxe used to prefix to the annual reports of the Scottish Commissioners in Lunacy he commented on the urgent need of elementary instruction in hygiene in our public schools, so as (in his own happy phrase) "to make every young man and young woman the intelligent custodians of their own health." The wholesome suggestion is bearing fruit in Italy. Your readers may remember the tragic death of the leading surgeon of the Tuscan school, Professor Colzi, as narrated in THE LANCET of April 25th, 1903, p. 1205. Well, the sum raised to form a perennial memorial of him has been devoted to the purpose well known to have been near his heart—that of training the youth at the public schools in the laws of health—and, with that object, to the bestowal of a prize, open to general competition, for the best manual of elementary hygiene. The judges were chosen from the "Società Toscana d'Igiene," who, after a careful perusal and comparison of the many treatises sent in, awarded the prize to Captain Giuseppe Cigliutti, M.D., of the regiment of mountain artillery quartered at Turin. The treatise, or manual, admirably well adapted for its purpose, will, it is understood, be introduced into the national schools and prizes will be periodically given for proficiency in its contents. A beginning has thus been made in a direction long lying unutilised in Italy, while Florence has "scored present running in Great Britain. In the course of discussion in the town council on the subject it was stated that during a period of three and a half years in Dundee 21 persons had fallen under the platform of the cars without any fatality occurring, while in Glasgow during the same period several fatalities had occurred. Unfortunately, since that statement was made Dundee's good record has been broken, as within the last few days a little girl in that city was knocked down and killed by having her neck caught between the cow-catcher and the ground. The larger number of fatalities in Glasgow can be understood when one considers the enormous development of the tramcar system in Glasgow. During the last 12 months 195,767,519 passengers were carried and the total mileage was 17,943,595. There is no doubt that the number of accidents has diminished since the first year or two after the introduction of electric cars and this can be attributed to the cultivation of the "car traffic sense" in the public and also to the increased expertness of the drivers. Although accidents will always occur it is possible that with an improved life-guard none of them need be fatal.

Greenock Vaccination Statistics.

The vaccination statistics for Greenock during 1904 should prove a somewhat indigestible morsel for the antivaccinationist to swallow. During the recent epidemic from figures at disposal it is shown that of 1000 persons in Greenock last year with good marks of early vaccination 3·4 took small-pox, while of 1000 with no marks or imperfect marks 19·8 took small-pox, or nearly six times as many. Again, 13·9 per cent. of successfully vaccinated persons took the disease in a severe form, while 62 per cent. of those with no marks suffered severely. Of 215 cases with good marks of early vaccination only four died, two of these from complications and of 50 persons with no marks 12 died, all from small-pox.

Peterhead New Fever Hospital.

On June 17th the foundation stone of the new infectious diseases hospital for the burgh of Peterhead was laid, with full Masonic honours, by Provost Leask. The hospital, which is situated on the north side of the town, beyond the fishing village of Buchanhaven, is being built after plans by the burgh surveyor. It is of the villa type, built in four blocks, including administrative and observation blocks, and will contain 16 beds. A small cottage hospital with two or three beds has served the necessities of the burgh for the last 20 years or more. The local authority, owing to the pressure put upon it by the Local Government Board, has, however, been compelled to make better provision in case of possible contingencies; and with a bequest of £1500 from the late Miss Hector, Prince-street, it has been able to put up a place that will not only meet the requirements of the town but will afford provision for the Deer District Committee dealing with patients in the more easterly part of its jurisdiction. The cost of the hospital, one block of which has already been built, is estimated at about £4000. Addressing the company after the ceremony had been performed, Provost Leask is reported to have said in the course of his speech:—"The old place was not much to look at. As a piece of elegant architecture it left something to be desired; but the outside was not always the best part of buildings, any more than of men and those who had put themselves, as he had done, to the trouble of learning from personal observation something about the internal arrangements of the old place, and who knew how many poor creatures had been tenderly cared for and nursed back to health in it, might be justified in hesitating to accept the change as an unmixed blessing, until experience had proved it to be so. Why, then, had it been found necessary to make this change? He would tell them. There was a body of gentlemen in Edinburgh who had been formed by a grandmotherly Government into a kind of moral policemen, with special reference to the preservation of public health throughout the country. For the performance of their duties any knowledge of local needs or local special circumstances was quite unnecessary. Indeed, the less they knew of these things the better they were able to carry out the cast-metal rules and regulations, and these they were privileged to apply and enforce with something resembling the despotism of a Russian Tsar. They seemed to have a belief that local men knew nothing about the requirements of their localities, or else could not be trusted to do their proper duties...... If he were asked to say something specially complimentary of their good town, he thought it would be that the fact that they had been able during the long period of upwards of 300 years to do without a hospital and for the last 20 years to supply their needs with what perhaps was the smallest epidemic hospital in the world, was proof of how remarkably healthy and desirable a place of residence Peterhead was. In vain they of the town council pointed out that Peterhead never had any fevers, and that they had already accommodation ample for their needs, and that should occasion ever arise they could satisfy any temporary requirements in a much better way; and in vain did they lay before them the difficulty that was being experienced in the matter of a suitable site, and so on."

June 27th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Typhoid Fever Epidemic in Newtownards.

IT is satisfactory to learn that the recent typhoid fever epidemic in Newtownards has been completely stamped out. The public health committee [illegible] the urban council to put before t[illegible]ard schemes for introducing a good water-supply from outside the town precincts.

The Small-pox Wards in Lurgan Workhouse.

Mr. R. Agnew, Local Government Board inspector, has been holding an inquiry on oath at Lurgan workhouse into a series of charges made by Mr. W. M'Mullan of Portadown in connexion with his treatment and that of his family when patients in the small-pox hospital of Lurgan workhouse. It would appear that a child of Mr. M'Mullan, who is an insurance agent, was on Sept. 28th, 1904, pronounced by Dr. J. A. Corbitt of Portadown to be suffering from small-pox and subsequently the medical officer of health of the district, Mr. J. L. Rowlett, intimated that the whole family would have to go to the workhouse hospital. The ambulance in which they were conveyed was a two-wheeled van, loose in the springs, and caused anyone sitting in it to be jolted. In his evidence Mr. M'Mullan said that there were not sufficient beds in the place so he, with the nurse, sought some in another part of the building. Here they found articles of bedding scattered about the floor and covered with feline filth, lime crumblings from the ceiling, and dust intermixed with mildew. The bed which the witness finally got was a wooden one with a mattress only about one and a half inches thick. There was no pillow for the child's bed and the mother had to use a bundle of rugs as a substitute. The child died next day at 4 A.M., Dr. J. S. Darling having only seen the patient once in the witness's presence. The clothes given to himself and family were damp and so also were the walls of the building. Whilst they were there the nurse was very ill with neuralgia and the witness attributed this to the dampness of the building. The three boys were forced to sleep in one bed, no other being provided, and one had to use a bundle of clothing for a pillow. Since leaving the hospital his wife had been very ill. There was a difference of medical opinion as to the prognosis in the case. Dr. Corbitt in his evidence said that the child had had the disease for nine days, had practically passed all the most dangerous stages, and was on the way to recovery when he saw the patient on the day of the removal. Dr. Darling, medical officer of the Lurgan workhouse, said that in his opinion the removal in the ambulance (which he considered an improper vehicle) did not make any difference to the child, who was suffering from confluent hæmorrhagic small-pox and would have died as soon at home. The child was already doomed to die before removal. He had great difficulty in fixing the responsibility on anyone for the unpreparedness of the hospital for the patients' reception and as a fact he did not know of it until ten days afterwards. Dr. Martha Adams, resident medical officer, said that the person responsible for the unpreparedness of the hospital was one of the nurses who disobeyed her in not going to the [illegible] Both she and a nurse declared that th[illegible] admitted and that there was no [illegible] taking place. Dr. Samuel Agnew of Lurgan said that he considered that a case of confluent small-pox, which was assuming a hæmorrhagic character, between the seventh and eighth days could not have passed the critical or dangerous stage. Several other witnesses having been examined, the inquiry ended on June 23rd. Mr. Agnew will put the evidence before the Local Government Board with which the decision rests.

June 27th.

account says that after the men had gone away the widow, who was some 50 yards distant, suddenly threw off her "sarce," made a rush for the funeral pyre, flung herself face downwards on it, and was burnt to death. No attempt was made to rescue her. There is little doubt that the whole affair was pre-arranged. The men do not in the ordinary course go right away before the cremation is completed and that a woman can run 50 yards and be burnt to death in the view of numbers of men without any attempt to stop her or to save her shows that the law was intentionally broken. These barbarous relics of an ancient custom will continue to recur unless the Government punishes more summarily and more severely the guilty relatives.

Cigarette Smoking among the Natives of India.

The tirade against cigarette smoking, which has been reported in one of the States of the American Union, is in curious contrast with the extraordinary development of this habit among the natives of India. The trade in cigarettes is increasing enormously. Last year no less than 584,000,000 were imported—an increase of 24·3 per cent.—and valued at 21 lakhs of rupees. The habit has caught on and the Indian demands the cheapest article. The cheapest cigarettes are imported from Shanghai and Ceylon—the former selling at R.1 A.9 pies 4 per 1000, whereas the Ceylon cigarettes fetch about 2½ annas per 1000 more. There is an enormous importation from the United Kingdom—some 385,000,000—which sell at about 5*s.* per 1000 and in addition some 111,000,000 are imported from the United States which sell at a little less. This is in excess of the local manufacture, which is considerable and increasing. If tobacco smoking in the form of cigarettes could replace the disastrous tastes for Indian hemp and cocaine it would be a blessing. Unfortunately, however, the fancy for cigarettes is rather the result of the higher wages now obtainable in all the chief towns and must be looked upon as a small luxury indulged in by the native as a consequence of his improved position.

June 9th.

Obituary.

ARTHUR DAVID GRIFFITHS, M.D. BRUX., L.R.C.P. LOND., M.R.C.S. ENG.

MEDICAL men are unfortunately not always sufficiently careful of their own health, although it is matter of common knowledge that the fatigues and anxieties of a busy practice are decidedly trying to the constitution. A sad example of sudden and untimely death is afforded by the case of Dr. Arthur David Griffiths of Bridgend, Glamorganshire, who was found to be seriously ill in his own house on the early morning of June 15th and expired in less than an hour after the discovery was made. Typhoid fever has been prevalent in Bridgend for several weeks, Mrs. Griffiths, who is still suffering from the disease, being among the first cases that occurred. Dr. Griffiths was attending 35 of these patients immediately before his death and the heavy work thereby entailed, together with anxiety respecting his wife, materially contributed to the fatal result. He had for some days been complaining that his heart was causing him trouble and on the evening before his death he telephoned to a relative in Bristol on the subject. At the inquest, which was held by Mr. Howell Cuthbertson, the district coroner, on June 16th, evidence was given by Miss Olive Griffiths, sister of the deceased, and by the nurse in attendance on Mrs. Griffiths. Mr. William E. Thomas of Bridgend, who is the family medical attendant, attributed the death to heart failure from overwork and a verdict to this effect was accordingly returned.

Dr. Griffiths who was 34 years of age at the time of his death, received his medical education partly in the Bristol school and partly in King's College, London, taking the diplomas of L.R.C.P. Lond. and M.R.C.S. Eng. in 1894. In 1897 he obtained the degree of M.D. at the University of Brussels. He commenced practice in the Forest of Dean in Gloucestershire, afterwards proceeded to Ramsgate, where he was an honorary surgeon to the Ramsgate Dispensary, and about four years later removed to Bridgend, where he held several appointments and had an extensive practice. In September, 1904, he had the misfortune to be made the object of a vile conspiracy planned by an electrician and his wife—a couple named Faithfull. The facts of the case are outlined in THE LANCET of Dec. 17th, 1904, p. 1733. The woman asked advice of Dr. Griffiths for some gynæcological ailment in 1903 and again in September, 1904, the husband being each time aware of the consultations. On the second occasion he rushed into the room during the examination of the patient, making serious allegations against Dr. Griffiths, who brought an action against him at the Swansea assizes for assault and slander. Neither the defendant nor his wife put in an appearance and a few days before the date of the trial their solicitor stated that he did not know their whereabouts. The jury awarded Dr. Griffiths £500 damages and the public opinion of the district was in sympathy with this vindication of his innocence. Dr. Griffiths, however, did not receive any payment in respect of the damages awarded him, while his legal expenses for the action amounted to about £205, and a fund to defray the latter was collected by a committee, consisting of the chairman and honorary secretaries of the Cardiff division of the British Medical Association and of the Cardiff Medical Society respectively, together with Dr. A. P. Fiddian of Cardiff and Dr. R. S. Stewart and Mr. W. Randall of Bridgend. Subscriptions to this fund were acknowledged by Dr. Fiddian in our columns on various occasions from Jan. 21st, 1905, to the beginning of April, and a considerable sum was in the result handed to Dr. Griffiths.

Of sunny, kindly personality, straight and genuine in every sense, he was one who instinctively was all that was honourable. He will be sadly missed not only by his more immediate friends but especially by the St. John Ambulance Brigade, in whose work he had long been enthusiastically and actively interested, and particularly so will this be the case in the No. 7 district in which he held staff rank. All his brother officers will assuredly feel a keen sense of personal loss in the untimely ending of a life which, to quote the motto of the order, was sacrificed "for service in the cause of humanity."

WILLIAM ALDER, L.S.A.

WE regret to announce the death of Mr. William Alder which took place at Monkwearmouth on June 19th. He had been in failing health for some time and had quite recently returned from a sojourn at Bournemouth which unfortunately had been without benefit. The deceased was an old Guy's Hospital man and a Licentiate of the Society of Apothecaries (1893). For two years after qualifying he served as surgeon on board the s.s. *Esquimaux* and s.s. *Eclipse*, vessels engaged in the whaling trade. After this he settled in Monkwearmouth and soon acquired a large practice and became very well known in the district. For a period of three years from 1896 he served on the town council but did not afterwards seek re-election. He was about 40 years of age. Death was due to chronic nephritis.

A HOSPITAL TENT.—A very interesting feature of the annual camp of the National Fire Brigades Union, held at the Crystal Palace, is the hospital tent, which has been fully equipped by Messrs. Carter of New Cavendish-street, W., on the most improved principles. The aseptic furniture and hospital appliances are of the latest description and members of the medical profession and visitors in any way interested in ambulance work should take the opportunity of inspecting the tent.

HEALTH CONDITIONS IN THE FAROE ISLANDS.—In his report for the year 1904 Mr. Villiers, British consul at Thorshavn, writes: "The condition of health in the islands cannot be regarded as altogether satisfactory. In spite of the natural salubrity of the mid-Atlantic isles, with their pure polar breezes, diphtheria and typhoid fever constantly appear in epidemic form in various villages, cases having occurred in all the larger islands in recent years. The health authorities find it difficult to enforce hygienic regulations among a population that seem to fail to realise the risk of infection. Sanitary arrangements are most primitive and what was possible without being pestilential when inhabitants were scarce and houses less clustered becomes impossible in the rapidly growing villages. Should fishing vessels enter and wish to have communication with the shore in places where infectious diseases are prevalent the master, when reporting his vessel to the quarantine officer, will in future be warned by him of the existing danger. Animals have also been attacked by disease, a blindness having befallen sheep on Ostero and on Sudero. The sheep had been free from this disease for many years. As the sheep here are neither folded nor herded blindness is fatally dangerous on the precipitous coasts of these islands."

again" in having been the prime mover in what may be hailed as an educational "Instauratio Magna."

The Medical Profession in Parliament.

In Latin countries the physician and the surgeon are oftener represented in the legislature than in those of Teutonic or Slav nationality and Italy in particular owes much of her best statesmanship to the intervention of such experts in her Chambers, Upper and Lower. Not only in general politics has she to thank her medical Premier Giovanni Lanza for much wise legislation and for the crowning service of "planting the colours of the House of Savoy on the Capitol," but, in special fields, like public health, she is indebted to Agostino Bertani, surgeon-general under Garibaldi, for a masterly "codice" which now forms part of the statute book. Baccelli, too, has done signal work in raising the standard of education, medical and lay, and has exercised a wise conservatism in arresting the retrograde faddism which has its place in Italy as elsewhere—"anti-vaccination"—to cite one instance out of many. The latest addition to the professional ranks in the Chamber of Deputies is that of Dr. Queirolo, professor of clinical medicine in the University of Pisa, just returned at a bye-election for that seat of learning by a sweeping majority. Dr. Queirolo, an active and able participant in the annual congresses of internal medicine, is welcomed by all parties as a distinct acquisition to the legislative body, in token of which he was entertained on June 22nd at a banquet by his constituents, including many of the Senatus Academicus and the leading citizens of Pisa and its province.

June 26th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Prevention of Tuberculosis among Negroes.

A SUBCOMMITTEE of 21 coloured physicians and clergymen has been organised by the New York Charity Organisation Society's Committee on the Prevention of Tuberculosis to fight tuberculosis among the coloured people of New York. The New York health board is coöperating with the movement and has placed its dispensary under the supervision of the medical members of the subcommittee for three evenings a week. A course of illustrated lectures treating of tuberculosis will be given shortly in the churches for coloured congregations. It is stated that there are between 60,000 and 65,000 coloured persons in New York city and that their death-rate from tuberculosis is 5·33 per 1000, as against 2·37 per 1000 among the whites.

Yellow Fever in the Isthmus of Panama.

Yellow fever is still present in the Isthmus of Panama. Several fresh cases have been reported by Governor Magoon, while a passenger from Colon to New York was found to be suffering from the disease upon his arrival in New York and has since died.

Patent Medicines.

Mr. Bok, the editor of the *Ladies' Home Journal*, has been carrying on for some time past a crusade against what he terms the patent medicine curse in America and has contributed an able letter on the subject to the *Journal of the American Medical Association* of May 20th. He points out that although various Bills have been introduced into the legislatures of several States having for their object the regulation of the sales of injurious patent medicines or the compulsory printing of the ingredients of these medicines on the label of each bottle, under penalty of fine or conviction, the passage of such Bills has been defeated by the active opposition of the proprietors of some patent medicines. The proprietors of patent medicines are, as a rule, rich, and by means of the expenditure of large sums they have been able to employ skilful lawyers to defeat measures aimed at their products. On the other hand, according to Mr. Bok, the chief advocates of the repressive Bills have been members of the Woman's Christian Temperance Union, whose zeal usually exceeded their discretion and whose advocacy, although well-intentioned, has consequently been ineffective. Members of the medical profession took no active part whatever in upholding Bills to control the sale of certain patent medicines. Mr. Bok believes that so long as the medical fraternity exhibits so little interest in the matter the public in general is not likely to urge effective legislation against injurious patent medicines. He therefore contends that medical men throughout the country should coöperate in this legislative work.

Rush Medical College, Chicago.

The announcement has been made that Rush Medical College, beginning with the session of 1905-06, will add a fifth year to the curriculum, which, however, for the present will be optional. The work of this additional year will be that of (*a*) a fellowship in one of the departments of the College, or (*b*) an interneship in the hospital under the following conditions—namely (1) that each student taking such work will be under the supervision of the Faculty, by whom the hospital in which the interneship is taken must be approved; (2) that the student must present evidence of thorough clinical work and, if possible, an exhaustive study of a selected group of clinical cases involving original work; and (3) that he will be required to pass a special examination at the end of the year. When he shall have successfully completed the fifth year he will be given the degree of Medicinæ Doctor *cum laude*.

June 21st.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Adoption of a Standard Time for India.

THE Government of India has issued instructions for the introduction of a standard time on all railways and in telegraph offices to come into force at midnight between June 30th and July 1st, 1905. This standard time will be exactly five and a half hours in advance of Greenwich and nine minutes in advance of the Madras time which has hitherto been in use for the railways. The Rangoon time will be six and one-eighth hours ahead of Greenwich and five minutes 23 seconds earlier than the present Rangoon time. It is not proposed to prescribe the extension of the new system beyond the sphere of the railways and telegraphs but there is little doubt that it will come ultimately to be adopted everywhere. Calcutta, Bombay, and Karachi now follow the local time of their respective longitudes and if there be a desire expressed the Government will be prepared to order the new standard at all Government institutions.

The Decline of the Plague Epidemic.

The plague mortality throughout India is happily on the decline. During the week ending May 27th the total fell from 35,992 to 23,088. The principal figures are: Punjab, 16,612 against 25,340; United Provinces, 2941 against 5132; Bengal 894 against 1069; Rajputana, 1171 against 2142; Bombay districts 441 against 585; Burmah 110 against 58; Kashmir 138 against 200; Bombay city, 497 against 594; Calcutta, 146 against 172; and Madras Presidency, 11 against 19. It will be noticed that the numbers of deaths and not cases are generally taken in India for the statistical records of plague. As a matter of fact the cases returned exceed the deaths by a very small proportion, by which it is not to be inferred that the mortality is so excessively high but simply that a very large number of cases fail to be discovered. Take, for example, the latest returns for Rangoon, which has had its first outbreak this season. From Feb. 5th to May 31st 1341 cases with 1197 deaths are recorded, a case mortality of 89 per cent. The real mortality from plague is about 75 per cent., so that it is almost certain some 250 cases of plague in Rangoon were undiscovered. The same experience is met with in Calcutta, Bombay, and other infected cities.

Extended Period of Study for the Medical Degree of the University of Calcutta.

It is reported that the period of study for the medical degree in the University of Calcutta is shortly to be raised from five to six years. It has been five years for a long time, even when the period of study in England was four years. Now a corresponding increase of one year is to be made in the local university. Few will question that it is a change in the right direction.

A Case of Suttee.

Now and again an instance of suttee is reported in some outlying district showing how the barbarous instinct still lingers amongst the superstitious and ignorant people who live outside the influence of Western control. On May 10th in a village named Shahjahanpur in the Sitapur district a man died and his body was burnt in the usual way. The account says that after the men had gone away the widow, was some 50 yards distant, suddenly threw off her rce," made a rush for the funeral pyre, flung herself face nwards on it, and was burnt to death. No attempt was de to rescue her. There is little doubt that the whole ir was pre-arranged. The men do not in the ordinary rse go right away before the cremation is completed and t a woman can run 50 yards and be burnt to death in view of numbers of men without any attempt to stop or to save her shows that the law was intentionally ken. These barbarous relics of an ancient custom will tinue to recur unless the Government punishes more mmarily and more severely the guilty relatives.

Cigarette Smoking among the Natives of India.

The tirade against cigarette smoking, which has been ported in one of the States of the American Union, is in rious contrast with the extraordinary development of this bit among the natives of India. The trade in cigarettes is creasing enormously. Last year no less than 564,000,000 ere imported—an increase of 24·3 per cent.—and valued 21 lakhs of rupees. The habit has caught on and the dian demands the cheapest article. The cheapest cigarettes e imported from Shanghai and Ceylon—the former selling R.1 A.9 pies 4 per 1000, whereas the Ceylon cigarettes tch about 2¼ annas per 1000 more. There is an enormous portation from the United Kingdom—some 385,000,000—hich sell at about 5*s.* per 1000 and in addition some 11,000,000 are imported from the United States which sell t a little less.' This is in excess of the local manufacture, hich is considerable and increasing. If tobacco smoking n the form of cigarettes could replace the disastrous tastes or Indian hemp and cocaine it would be a blessing. nfortunately, however, the fancy for cigarettes is rather the esult of the higher wages now obtainable in all the chief owns and must be looked upon as a small luxury indulged n by the native as a consequence of his improved position.

June 9th.

Obituary.

ARTHUR DAVID GRIFFITHS, M.D. BRUX., L.R.C.P. LOND., M.R.C.S. ENG.

MEDICAL men are unfortunately not always sufficiently careful of their own health, although it is matter of common knowledge that the fatigues and anxieties of a busy practice are decidedly trying to the constitution. A sad example of sudden and untimely death is afforded by the case of Dr. Arthur David Griffiths of Bridgend, Glamorganshire, who was found to be seriously ill in his own house on the early morning of June 15th and expired in less than an hour after the discovery was made. Typhoid fever has been prevalent in Bridgend for several weeks, Mrs. Griffiths, who is still suffering from the disease, being among the first cases that occurred. Dr. Griffiths was attending 35 of these patients immediately before his death and the heavy work thereby entailed, together with anxiety respecting his wife, materially contributed to the fatal result. He had for some days been complaining that his heart was causing him trouble and on the evening before his death he telephoned to a relative in Bristol on the subject. At the inquest, which was held by Mr. Howell Cuthbertson, the district coroner, on June 16th, evidence was given by Miss Olive Griffiths, sister of the deceased, and by the nurse in attendance on Mrs. Griffiths. Mr. William E. Thomas of Bridgend, who is the family medical attendant, attributed the death to heart failure from overwork and a verdict to this effect was accordingly returned.

Dr. Griffiths who was 34 years of age at the time of his death, received his medical education partly in the Bristol school and partly in King's College, London, taking the diplomas of L.R.C.P. Lond. and M.R.C.S. Eng. in 1894. In 1897 he obtained the degree of M.D. at the University of Brussels. He commenced practice in the Forest of Dean in Gloucestershire, afterwards proceeded to Ramsgate, where he was an honorary surgeon to the Ramsgate Dispensary, and about four years later removed to Bridgend, where he held several appointments and had an extensive practice. In September, 1904, he had the misfortune to be made the object of a vile conspiracy planned by an electrician and his wife—a couple named Faithfull. The facts of the case are outlined in THE LANCET of Dec. 17th, 1904, p. 1733. The woman asked advice of Dr. Griffiths for some gynæcological ailment in 1903 and again in September, 1904, the husband being each time aware of the consultations. On the second occasion he rushed into the room during the examination of the patient, making serious allegations against Dr. Griffiths, who brought an action against him at the Swansea assizes for assault and slander. Neither the defendant nor his wife put in an appearance and a few days before the date of the trial their solicitor stated that he did not know their whereabouts. The jury awarded Dr. Griffiths £500 damages and the public opinion of the district was in sympathy with this vindication of his innocence. Dr. Griffiths, however, did not receive any payment in respect of the damages awarded him, while his legal expenses for the action amounted to about £205, and a fund to defray the latter was collected by a committee, consisting of the chairman and honorary secretaries of the Cardiff division of the British Medical Association and of the Cardiff Medical Society respectively, together with Dr. A. P. Fiddian of Cardiff and Dr. R. S. Stewart and Mr. W. Randall of Bridgend. Subscriptions to this fund were acknowledged by Dr. Fiddian in our columns on various occasions from Jan. 21st, 1905, to the beginning of April, and a considerable sum was in the result handed to Dr. Griffiths.

Of sunny, kindly personality, straight and genuine in every sense, he was one who instinctively was all that was honourable. He will be sadly missed not only by his more immediate friends but especially by the St. John Ambulance Brigade, in whose work he had long been enthusiastically and actively interested, and particularly so will this be the case in the No. 7 district in which he held staff rank. All his brother officers will assuredly feel a keen sense of personal loss in the untimely ending of a life which, to quote the motto of the order, was sacrificed "for service in the cause of humanity."

WILLIAM ALDER, L.S.A.

WE regret to announce the death of Mr. William Alder which took place at Monkwearmouth on June 19th. He had been in failing health for some time and had quite recently returned from a sojourn at Bournemouth which unfortunately had been without benefit. Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in June the following candidates passed in the subjects indicated:—

Surgery.—A. Beeley (Section II.), Leeds; G. N. Biggs (Sections I. and II.), St. Thomas's Hospital and Durham; V. H. Blake (Sections I. and II.), St. George's Hospital; H. R. Grellet (Section II.), Guy's Hospital; F. E. Gubb (Section II.), Royal Free Hospital, A. H. Hughes, Bristol; H. A. Parker (Section I.), St. Thomas's Hospital; J. W. Peatt (Section I.), London Hospital; T. R. St. Johnston (Sections I. and II.), Birmingham; N. A. Stutterheim (Sections I. and II.), Utrecht; A. L. Walters (Sections I. and II.), St. Thomas's Hospital; and J. M. Wilson, Middlesex Hospital.

Medicine.—M. B. Dawson (Section II.), Middlesex Hospital; F. E. Gubb (Sections I. and II.), Royal Free Hospital; P. A. Hendley (Sections I. and II.), St. Mary's Hospital; F. J. Macnhal (Sections I. and II.), Liverpool; [illegible] and II.), Birmingham; and J. M [illegible]

Forensic Medicine.—J. J [illegible] Hendley, St. Mary's Hospital; F. [illegible] y, London Hospital; G. B. Messen [illegible] B. Miles, London Hospital; R. H. Terry, Guy's Hospital; and J. M. Wilson, Middlesex Hospital.

Midwifery.—G. N. Biggs, St. Thomas's Hospital and Durham; V. H. Blake, St. George's Hospital; H. S. Burnell-Jones, Cardiff, Leeds and London Hospital; W. L. Crabtree, Leeds and Charing Cross Hospital; E. B. Miles, London Hospital; and H. M. Waller, St. Bartholomew's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—A. Beeley, J. J. Commerell, W. L. Crabtree, M. B. Dawson, H. R. Grellet, F. E. Gubb, P. A. Hendley, and A. H. Hughes.

TRINITY COLLEGE, DUBLIN.—At the final examination in medicine held in Trinity term the following candidates were successful:—

Section A.—Cecil Conyngham, Edward C. Stoney, Albert T. J. M'Creery, Henry P. Hart, John W. Lane, Eleanor E. Finegan, Arthur E. Knapp, Wallace D. Mitchell, Herbert R. N. Fowler, George H. Stack, John Gray, and James G. M. Moloney.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE: THE BACTERIOLOGICAL DEPARTMENT.—During the last 12 months 1474 specimens have been examined in the bacteriological department of the University of Durham College of Medicine, Newcastle-upon-Tyne, showing an increase of 352 over the previous year. The great majority of the specimens were examined for the various county councils and public institutions in the neighbourhood. Out of 774 specimens of sputum examined for tubercle bacilli, 39 per cent. were found to be positive. Out of 421 cases of suspected diphtheria, 38 per cent. were found to be positive, whilst from 149 specimens of blood from suspected enteric fever 47 per cent. were positive. 48 samples of water were examined quantitatively for bacteria and six samples of milk [illegible] Urine was examined in 25 cases for [illegible] with five positive results. Ten specimens of blood were examined for anthrax with seven positive results. One sample was examined for glanders with a positive result and one sample of brawn was examined for bacillus enteritidis with a positive result.

NATIONAL SANATORIUM FOR CONSUMPTION AND DISEASES OF THE CHEST.—The annual general meeting of governors of the National Sanatorium for Consumption and Diseases of the Chest at Bournemouth in Hampshire was held in London on May 11th at the Westminster Palace Hotel, the Earl of Eldon (the president of the association) being in the chair. This sanatorium was founded in 1855 for the reception of patients from all parts of the kingdom. The report presented at the meeting showed that the ordinary income for the year ended Dec. 31st, 1904, amounted to £2999 and the ordinary expenditure to £3094. The balance sheet showed a deficit of £426 and in addition to this indebtedness there were at the end of the year several accounts still unpaid amounting to over £1000. In April, 1904, the committee came to the conclusion that owing to the increasing demands for admission an extension of the institution could not be longer delayed if its work was to be efficiently carried on. The carrying out of these necessary improvements caused a temporary interruption in the reception of patients but owing to their completion the sanatorium is now able to receive 85 patients (43 men and 42 women), the dining rooms have been enlarged, six more baths have been added, and sash windows in the sleeping apartments have been replaced by casements. The outlay incurred, including furnishing, amounted to £3000, towards which only about £2000 have been contributed, and it is mainly on this account that the institution is so heavily in debt. The sanatorium is now ering upon the fiftieth year of its existence and in er to celebrate the event the committee is making a cial jubilee appeal for the extinction of the debt for new annual subscriptions, so that the permanent ome may be sufficient to meet modern requirements. The ients remaining in the sanatorium on Jan. 1st, 1904, were men and 37 women and during the year 104 men and 116 men were admitted. There were three deaths and among patients of both sexes who were discharged the results re: much improved, 78; improved, 105; no improvement, . The bankers of the institution are Messrs. Barclay and ., Limited, Pall Mall East, London, and the Wilts and rset Bank, Bournemouth. Inquiries should be addressed the Secretary at the National Sanatorium, Bournemouth.

British Electro-Therapeutic Society.—Dr. nald Baynes, President of the British Electro-Therapeutic ciety, took the chair at the annual dinner of this society, ld in the Prince's Rooms of the Criterion Restaurant, ndon, on June 23rd. The society consists of about 0 medical men interested in the treatment of disease by ectrical methods. One of the objects of the society is educate the profession in the matter of electro-therapeutics d to endeavour to put a stop to the present encourage- ent given by prominent members of the profession to the nployment of unqualified assistance in the treatment of eir patients by electricity and other physical agents. The uncil of the society is now engaged in taking into very rious consideration medical electrical treatment by un- ualified persons and it is hoped that its efforts may meet ith some success. Monthly meetings are held and in the urth annual report of the council it is stated that the verage attendance of the members is very satisfactory. fter the loyal toasts had been duly honoured the chairman roposed the toast of "The British Electro-Therapeutic ociety." He entered in some detail into the grievances of he members of the society and particularly referred to ten edical men whose names were announced as recommending certain individual for the treatment of obesity by the com- ined light treatment, of nervous troubles by blue lights, and f gout, rheumatism, sciatica, lumbago, &c., by the combined bath. Dr. H. Lewis Jones, in responding to this toast, advised the members of the society to concentrate their efforts in the direction of learning how to cure diseases that now were considered incurable. He mentioned with regret that Guy's Hospital had issued a circular from its light department offering to treat paying patients at an inclusive fee of six guineas, stating as a reason that the hospital wished to pay for certain apparatus. Other toasts followed and the proceedings terminated at a late hour.

Hospital Extension at Tottenham.—Two foundation stones of the extensions of the Tottenham Hospital were laid on June 20th—one of a north wing to the front of the hospital as a residential block for the resident medical and surgical staff in its lower part and in a self-contained upper part for a portion of the nursing staff, and the other of an extension to the rear of the hospital, consisting of two new wards and an operating theatre to be called the Drapers' Block. The Lord Mayor and Sheriffs, who drove in state from the Mansion House to the hospital, were received by Sir Francis Cory-Wright, chairman of the hospital, with representatives of the hospital board of management and medical staff. Sir F. Cory-Wright in his address to the Lord Mayor before the stone-laying said that when six years ago the hospital was reconstructed it was in a languishing condition, with only 17 patients to occupy the 73 beds. Since then the needs of the district had grown to such a great extent that it had become absolutely necessary to increase their accommodation. It was his belief that one day their institution would become a second London Hospital. The King Edward's Fund and the Drapers' Company had come forward with most generous support and they looked forward confidently to raising the sum of £6000, which would enable them to bring up the number of beds to 130. The Lord Mayor, who was presented with a silver trowel by Mr. Rowland Plumbe, the architect, on behalf of the hospital, declared the foundation stone of the front block well and truly laid. A vote of thanks to the Lord Mayor and Sheriffs was proposed by Mr. J. P. Beavan, honorary treasurer to the hospital, and seconded by Mr. J. Cloudsley. The vote was acknowledged by the Lord Mayor, and on behalf of the sheriffs in a felicitous speech by Sheriff Vezey Strong. A similar ceremony was performed in the rear of the building, where the foundation stone of the Drapers' Block was laid by Mr. J. Tolhurst, the Master of the Drapers' Company, a silver trowel being also handed to him by Mr. Rowland Plumbe. The chairman of the hospital in his address stated that towards the £20,000 required for the present extensions the Drapers' Company had given £6000. A vote of thanks to the Worshipful Master and Court of Assistants was proposed by Mr. John Langton, chairman of the medical committee, and seconded by Mr. Charles Churchill, vice-chairman of the hospital. The members of the medical staff were present in their academic robes and a large concourse of the supporters of the hospital witnessed the ceremony. Afterwards the guests inspected the wards of the hospital and walked through the grounds, which extend to several acres. The extension includes not only the two new blocks but also the enlargement of two of the present wards, containing 12 beds, so that they will hold 24 beds each; an x ray and electrical department, and a new pathological department, consisting of a spacious museum and a laboratory. The latter part of the scheme is largely owing to the generosity of one of the members of the honorary surgical staff.

Donations and Bequests.—Dr. Thomas Trollope, of St. Leonards-on-Sea, by will bequeathed £1000 to the Hastings and St. Leonards and East Sussex Hospital; £1000 to the vicar and churchwardens of Christ Church, St. Leonards-on-Sea, for the benefit of the sick and poor of the parish; and after making further bequests, provided that his estate be sufficient, a further £1000 to the East Sussex Hospital.—The Zunz trustees have granted to the Friedenheim Home, Hampstead, £3000 on condition that the sum of £600 is raised by other subscribers.—An anonymous donation of £500 has been sent to the Bristol Royal Infirmary.—Miss Symers of St. Helen's has given £1000 to the building fund for enlarging the nurses' accommodation at the Victoria Hospital, Dundee.

Hospital Appeals.—In March last an appeal on behalf of Guy's Hospital was issued asking first, for £100,000, the balance of the funds sought to be raised in 1901 and urgently needed to carry Guy's Hospital through present straits; and secondly, for annual contributions of sufficient amount to enable the hospital to maintain its present work in continued efficiency. This appeal has been met in many quarters by most generous help. Towards the £100,000 required on capital account the response up to date is, roundly, £49,000. But in analysing this sum we find some striking and curious facts. 138 contributors, in sums ranging from £25 to £5000, gave about £46,000. 220 contributors of sums under £25 subscribed rather more than £1000 and the balance is provided by contributions from the million shillings fund. The appeal has been sent into the offices and homes of over 100,000 of the well-to-do classes in the metropolis and in addition personal letters have been addressed to some thousands of those who were considered likely to subscribe, yet a direct response has been received from only 358 persons. Mr. H. Cosmo O. Bonsor, the treasurer, in a letter which we have received from him, earnestly asks those who "have this world's goods" to "help us now and also to remember Guy's Hospital in their wills. Experience has taught us how much the permanence and prosperity of our charitable foundations depend on this kindly forethought for the needs of others on the part of those who are no longer among us."—The committee of University College Hospital has issued a special appeal for funds, contributions from the public not being sufficient to meet the requirements of the hospital. Quite recently it has been necessary to sell out stock to produce £2000 to pay pressing tradesmen's bills. The committee finds itself placed in further difficulty owing to the new building having been handed over to it in an unfinished state by the executors of the late Sir J. Blundell Maple. The sum placed by him at the disposal of the executors for the completion of the building has been exhausted, and they have no power to expend further money on it. The committee is therefore compelled to provide a sum of about £3200 for the execution of absolutely essential work. The committee most earnestly appeals for donations to enable it to meet the cost of this work and also for contributions, in the form of annual subscriptions and donations, for the maintenance of the hospital so as to avoid further sales of stock and the consequent diminution of the permanent income of the charity. The appeal is signed by the Duke of Bedford, President, Lord Monkswell, treasurer, and the chairman and vice-chairman of the hospital committee.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

New Medical Bills.

AT this advanced period of the session it is useless to expect to make progress with Bills introduced by private members but there is an obvious advantage in having the text of a Bill printed and circulated even although the prospect of legislation is not immediate. No doubt it is with a view to gaining this advantage that Sir JOHN BATTY TUKE has this week introduced two Bills affecting medical men and dentists. The object of one is to prohibit joint-stock companies from acting as physicians, surgeons, or medical practitioners, and the other is to prohibit joint-stock companies from carrying on practice as dentists except by means of duly qualified persons.

Medical Affairs in Scotland.

When the Scotch estimates were considered in the House of Commons on June 22nd some references were made to medical affairs in the northern kingdom. It was a matter of complaint that there was only one Local Government Board medical inspector, whereas Ireland has seven, and the suggestion was put forward that if the Board did its duties more thoroughly many schools, particularly in the Highlands and Islands, would not need to be closed so frequently on account of epidemics. In his reply on the debate the LORD ADVOCATE explained that so far as the Local Government Board was aware one medical inspector was able sufficiently to discharge the duties that fell upon him, and there was no justification for appointing additional inspectors. Another complaint was that humanised lymph was still used in some districts. The LORD ADVOCATE stated, however, that *some parents preferred humanised lymph rather than calf lymph* and the Board fell in with their wishes. For those vaccinators who asked for it a small supply of humanised lymph was always available.

HOUSE OF COMMONS.

MONDAY, JUNE 26TH.

Removals from Medical and Dental Registers.

Mr. WEIR *asked the Secretary of State for the Home Department* whether having regard to the fact that during recent years 20 names had been struck off the Medical Register for infamous conduct in a professional respect, whilst six names were removed from the Dental Register for a similar cause, he would state in how many instances the names were removed on charges of adultery.—Mr. AKERS DOUGLAS replied: From the Medical Register in four cases; from the Dental Register in none.

TUESDAY, JUNE 27TH.

Lymph Calves as Food.

Mr. SYDNEY BUXTON asked the Secretary to the Local Government Board whether the carcasses of calves inoculated for lymph at the Local Government Board vaccine station were sold for food in London, and if so, whether he would give instructions to have such carcasses destroyed instead of being returned to the contractors.—Mr. GERALD BALFOUR answered: As I stated in reply to a question put to me by the honourable Member for Ross and Cromarty on the 30th ult. I am advised that there is no evidence whatever that the carcasses of animals used for the [illegible] thoroughly examined by a veterinary surgeon *before being allowed to be sold for* food.

Coccidiosis in Rabbits.

Mr. MORRELL asked the President of the Board of Agriculture whether he had information as to the existence of disease of the nature of tuberculosis affecting the liver of the rabbit, specially prevalent this year, and if so whether he would cause inquiry to be made and information laid before the Commission on Tuberculosis as being a disease possibly affecting the food of man. Mr. AILWYN FELLOWES said: *I am advised that the disease to which my honourable friend* refers is caused by an animal parasite and that it is not of the nature of tuberculosis. Its correct name is coccidiosis. In these circumstances it does not appear to be necessary for any communication to be made to the Royal Commission on Tuberculosis on the subject. It is not considered *by the Board's veterinary officers* that the disease is attended with any danger to man but I propose to bring the matter under the notice of the Local Government Board.

STRAITS SETTLEMENT, MUNICIPALITY OF THE TOWN OF SINGAPORE.—Assistant Municipal Health Officer, unmarried. Salary £400 per annum.

SWANSEA GENERAL AND EYE HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with board, apartments, washing, and attendance.

WESTERN GENERAL DISPENSARY, Marylebone road, N.W.—Junior House Surgeon. Salary at rate of £80 per annum, with board,

Broad Sanctuary, S.W.—Medical Registrar.

NTS COUNTY HOSPITAL.—House Physician, unmarried. Salary £65 per annum, rising to £75, with board and residence, &c.

THE Secretary of State, Home Office, S.W., gives notice that in consequence of the death of Dr. James Murphy the appointment held by him of Medical Referee under the Workmen's Compensation Acts, 1897 and 1900, for Sunderland and Seaham Harbour County Court Districts in County Court Circuit No. 2 is vacant.

Births, Marriages, and Deaths.

BIRTHS.

BARENDT.—On June 25th, at 65, Rodney street, Liverpool, W., the wife of Frank H. Barendt, M.D. Lond., F.R.C.S. Eng., of a son.

CREE.—On June 23rd, at St. Hilary terrace, Stoke, Devonport, the wife of Major Gerald Cree, R.A.M.C., of a son.

LAWSON.—On the 24th June, at 12, Harley street, Cavendish square, W., the wife of Arnold Lawson, F.R.C.S., of a son.

NEWTON.—On June 27th, at Fairfield, Chelmsford, the wife of H. W. Newton, M.R.C.S., &c., of a son.

PEMBREY.—On June 16th, at Mount Pleasant, Scrase's hill, Hayward's Heath, the wife of M. S. Pembrey, M.D., of a daughter.

TURNER.—On June 25th, at Westbury, Purley, Surrey, the wife of S. Duke Turner, M.D., D.P.H., of a daughter.

MARRIAGES.

CARMICHAEL—CLAYTON.—On June 24th, at St. Mary's Church, Long Ditton, Henry Carmichael, M.B., C.M., of The Elms, East hill, Wandsworth, to Margaret Lydia, daughter of Charles H. Clayton.

GATES—FOWLER.—On June 24th, at All Saints, Great Marlow, Edward Alfred Gates, M.D., M.R.C.P., to Mary Elizabeth, third daughter of the late Major General Fowler, R.E.

DEATHS.

26th, at Buckingham Palace-mansions, James
M.D., LL.D., C.S.I., Surgeon General with
ndia, Hon. Surgeon to the King, aged 76.

TURNBULL.—On June 22nd, at Lansdowne crescent, W., Alexander Turnbull, M.D., Inspector General of Hospitals and Fleets, R.N. (retired), aged 67.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE MISSION TO LEPERS IN INDIA AND THE EAST.

IN the thirtieth annual report of this society continued extension of work is recorded. Including the inmates of the new asylums opened last year the mission is now supporting, or in some way relieving, about 7000 lepers and their children. Perhaps the most hopeful branch of the society's work is the rescue of the untainted children of leprous parents for whom 20 special homes are maintained. One of the events of the past year was the opening of the new asylum at Tarn Taran in the Punjab. This institution takes the place of a miserable collection of huts in which the lepers of that district formerly existed in misery and squalor. The asylum was opened by the Lieutenant-Governor of the Punjab and the sympathy of the authorities with this benevolent work was further shown by the visit of Sir Andrew Fraser to two of the Bengal asylums of the mission, in the largest of which 700 lepers and their children are now provided for. The report tells of interesting and on the whole very hopeful experiments with leprolin, the new serum discovered by Captain E. R. Rost of the Indian Medical Service. A number of cases treated with leprolin have apparently received relief; they are being tested in observation wards with a view to determine whether the improvement is permanent. The mission is carrying on work in as many as 72 stations in India, China, Japan, and other parts of the Far East, their total expenditure for the year being £19,800.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—Can any of your readers tell me of a home where a male patient suffering from paralysis involving the excretory organs can be admitted and taken care of? He is in a position to pay about £3 3*s.* per week inclusive.

I am, Sirs, yours faithfully,
BERTRAM ADDENBROOKE.
34, Mill-street, Kidderminster, June 20th, 1905.

A NEW METHOD OF GENERATING FORMALDEHYDE GAS FOR FUMIGATING PURPOSES.

THE high value of formaldehyde gas as a fumigating agent has to some extent been discounted by the complicated and expensive generators which are very liable to get out of order and by the length of time required to generate sufficient gas to fumigate an apartment. To overcome these difficulties the vapourisation of solid polymerised *formaldehyde*, paraform, by means of a burning charcoal cone was resorted to. Unfortunately this proved an inefficient substitute owing to several causes, chief of which were the absence of moisture, the complete combustion of a large part of the paraform, and the volatilisation of the paraform as such instead of decomposing into simple gaseous formaldehyde, and the risk of setting fire to carpets and furniture. These various difficulties appear to have been overcome by Mr. Henry V. Walker of the Department of Health, Brooklyn, U.S.A., according to the Journal of the American Chemical Society of March, 1905, p. 277. He suggests a method of liberating formaldehyde gas from its aqueous solution by the addition of lime as a dehydrating agent. In order to prevent the calcium hydroxide which goes into solution from converting the formaldehyde into alcohol and acid aluminium sulphate is added which forms an insoluble sulphate with the lime. In practice the mixture is made by dissolving 20 to 25 pounds of commercial aluminium sulphate in five gallons of hot water and mixing this solution with 15 gallons of 40 per cent. formaldehyde solution. Eight fluid ounces of this mixture and one pound of lime are used for every 1000 cubic feet to be fumigated. The lime should be in the form of coarse powder or lumps and it is essential that it should slake rapidly with cold water. This method has the advantages of not requiring any special apparatus, of cheapness, and of freedom from danger of fire. In municipal practice it has given excellent results, over 90 per cent. of successful fumigations, as tested by bacillus pyocyaneus, being obtained. This high degree of success is doubtless largely due to the great rapidity with which the gas is evolved, a sufficient quantity to fumigate an ordinary apartment being liberated in from five to ten minutes.

TO DEADEN SOUND.

To the Editors of THE LANCET.

SIRS,—In 1894 I suggested a simple expedient for the prevention of insomnia. It was to exclude sound and light by lying on the edge of the pillow which fold from the back of the neck over the ears and eyes.

I am, Sirs, yours faithfully,
Welbeck-street, W. E. D. MAPOTHER.

◆

S.—We cannot publish our correspondent's letter as it amounts to a reflection upon the ability and honesty of the whole nursing profession founded upon individually unfortunate experience. Nurses detected by a patient or a patient's friends in such conduct should at once be reported to the medical man in charge of the case and to any nursing establishment or institution with which they may be connected.

Medico.—The professional prospects of a medical man starting practice in the district named are not very good. Most of the districts are sparsely populated, while in the townships medical men are already established. Canada turns out highly qualified medical men every year from the excellent Universities of Montreal and Toronto.

Senex.—The subject has been dealt with on several occasions recently in our columns and we think that to make further allusion to it will be inadvisable. Undoubtedly the situation constitutes one of the drawbacks of medical service in the army, but perpetual ventilation of the grievance does not seem to us likely to lead to reform.

Coincidence has written us an interesting letter but although it is interesting it has failed to convince us.

C. S.—We fear the suggestion is hardly practicable.

ERRATUM.—In our table of "Dispensaries" given in "THE LANCET Hospital Sunday Fund Supplement," published on June 17th, p. 1656, the number of out-patients' visits at Kilburn, Maida Vale, and St. John's Wood Dispensary should have been 7958 and not 5958 as there given.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.).

TUESDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.).

N[illegible] SED AND EPILEPTIC (Queen-[illegible] M. Dr. Collier: Peripheral Neuritis, Toxic.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only. AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND, IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1905, which was completed with the issue of June 24th, and the Title-page to the Volume, are given in this number of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1905 will be ready shortly. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

AUTOMATIC FLUSHING OF THE STOMACH IN CERTAIN CASES OF VOMITING.

Delivered at St. George's Hospital,

By SIR WILLIAM H. BENNETT, K.C.V.O., F.R.C.S. ENG.,
SENIOR SURGEON TO THE HOSPITAL.

GENTLEMEN,—In an address published in 1900[1] I dealt with some points connected with vomiting as met with in surgical work which seemed to me to be of interest. What I have to say to-day is the outcome of further experience in the same direction and may be taken for practical purposes as a sequel to the observations I then made.

Speaking generally it will, I am sure, be found that an honest respect for traditional methods of treatment is worthy to be encouraged, but a respect of this kind is quite different from the slavish adherence to manners and methods which, at all events in many cases, if not harmful, are useless and ought rapidly to become obsolete. This observation applies with singular aptness to the treatment of certain forms of vomiting not uncommon in ordinary clinical work, which is prone to occur in many abdominal cases, with and without operation, in which, for some reason or other, the normal functions of the intestines are so disturbed that frequent rejections of the stomach contents take place. Such vomiting may be met with in intestinal obstruction, in true peritonitis, in the pseudo-peritonitis following certain abdominal operations and injuries, and other conditions of a like nature which I need not detail. The traditional method of treatment in cases of this kind is to abstain as far as possible from giving the patients anything by the mouth in the way of liquid, upon the assumption that the less fluid there is in the stomach the less the stomach will tend to reject its contents and so the less will be the tendency to vomiting, the offensive character of the stomach contents as a factor in the production of vomiting being ignored. This is a pretty generally accepted method in the schools. Now, in all patients suffering from this distressing condition the great misery complained of is the intense thirst, because, as can readily be understood, the frequent ejection of fluid from the stomach in excess of that which is put into it must very rapidly lead to a general drying up of the body moisture and so engender a thirst of the most painful type. To obviate this intense discomfort—I mean the discomfort of thirst—attempts have been made by the use of large injections of water into the bowel, but more commonly simply by the giving through the mouth of very small quantities of fluid, either hot water in sips, or certainly not in larger quantities at one time than a tablespoonful, or by the administration of very small pieces of ice which are allowed to dissolve on the tongue. The first of these methods does to some extent, although not completely, tend to assuage thirst but it does not alter the character of the vomit, a most important point. The remaining two plans may be set aside as of little account in the assuaging of thirst as their effect is practically *nil*, mainly because the abstraction of fluid from the body generally by the ejections from the stomach is so far in excess of the fluid added by these methods that it must be clear to the meanest comprehension that no relief to thirst worth mentioning can possibly be achieved by them. Vomiting of this type, even supposing that there is not intestinal obstruction, is a very serious condition, and as a matter of fact a certain percentage of patients who reach the period of the "stinking vomit," which, although very frequently called stercoraceous,[2] that is to say containing fæcal material, is not always so, die not from the disease which produces the vomiting, but from the exhaustion, distress, and disgusting effect of the process of vomiting such offensive material. Obviously, therefore, some means should be sought by which this vomiting can either be arrested or the vomit be so altered in its composition as to be less offensive, so that the disgust engendered by its occurrence can be avoided. The question then arises how is this to be brought about. The matter is not difficult, although I must confess to having learnt it from a patient who took the treatment of his case into his own hands, against the advice of his medical attendants, of whom I was one. It consists, in fact, instead of restricting the amount of fluid given, of allowing the patient to drink as much as he chooses of ordinary cold or tepid water or some other perfectly unirritating fluid. As the thirst in the first instance is the main thing to be obviated, plain water is the best, because it is more quickly absorbed than any other liquid. The effect of the administration of water in this way in cases of the kind is really to bring about a very frequent automatic washing out of the stomach and it will be found by the time the patient has taken, say, a pint or one and a half pints of water, which he will greedily do, that the vomit, although occurring quite as frequently as, or perhaps more frequently to begin with than, before, becomes clear; it loses its smell, the offensive taste is gone, and the patient's disgust is entirely removed. In such a case it is a revelation to watch the change that comes over a patient's countenance as he is allowed to quench his thirst and as the vomiting, after taking free libations of water, becomes inoffensive to the taste and smell. The look of disgust and distress which is such a notable characteristic in the ordinary circumstances, is replaced, as the stomach is cleansed each time the vomiting of the recently swallowed water occurs, by a look of contentment and repose which is hardly credible unless it has been actually seen. This method, of course, as I have already hinted, is entirely contrary to orthodox methods but, as I have also said, it is necessary from time to time to reconsider our position with regard to orthodox teachings, because there is no doubt that in many cases tradition—we might almost say superstition—lends such an importance to some old-fashioned methods that they are adhered to with a blind confidence which is not particularly creditable to the intelligence of those who follow them.[3]

CLINICAL EXAMPLES.

The following cases should afford enough clinical evidence of the correctness of the foregoing observations.

CASE 1.—A man, about 68 years of age, of strong physique, developed evidences of partial intestinal obstruction of a chronic kind which finally led to an exploratory operation being made, with the result that there was found an apparently malignant mass involving the large intestine, dragging also into itself a knuckle of the ileum. A number of secondary masses were scattered about the abdomen and the disease was clearly so extensive in its distribution that no good whatever could be done by an extension of the operation, more particularly as it appeared very doubtful whether a condition of complete obstruction would finally accrue although it was possible that it might do so. In these circumstances nothing was done with the local condition; the abdominal wound was closed, and the patient was told as candidly as possible what the state of affairs was. Within three or four days of the operation an increased obstruction ensued and vomiting commenced. This in the usual course was followed by the intense thirst I have referred to; by degrees the vomit became stinking, containing sometimes a litttle blood, the result of the straining; and the taste, as the patient said, was something horrible. From being a comparatively robust looking person at the onset of the vomiting, in three or four days he was an emaciated, miserable-looking object who was only "longing to die to escape," as he said, "from this horrible thirst and taste and stink." Those were his own words. Up to that time he had been treated in the orthodox way, with the restriction of fluid in the manner that I have mentioned earlier in this lecture. At last the thirst became so terrible that the patient said, as he was going to die, or felt that he was going to die, he would prefer to quench his thirst, even if it made him vomit more; he therefore not only begged but insisted upon having as much water to drink as he wanted. Seeing the desperate condition in which he seemed to be, and seeing the confidence that he felt of being more comfortable if he wer allowed to follow this plan I acquiesced and we allowed him to have by his bedside a glass of water, which was continually filled as fast as he chose to drink it. The amount of fluid taken in the first two or three hours was very large and of course the vomiting was frequent. But, as I have already mentioned, very rapidly the rejected contents of the stomach, instead of being dark and ill-smelling, became clear, there was no effort involved in the vomiting, and the water which he drank, after resting for a certain time in his stomach, regurgitated from his mouth, upon which he almost immediately took some more water in the ordinary way. Before he had been on this line of treatment a few hours the thirst had entirely disappeared and he "thanked God" for the comfort which followed. By degrees the vomiting became less and at the end of the third day from the commencement of this treatment, instead of being dead, as appeared likely at the commencement, he was manifestly getting better, and as a matter of fact his bowels resumed their normal functions for a period; he lived for some time, taking free libations of water, and latterly taking a little liquid food, vomiting about once in 24 hours only, and being in perfect comfort. Finally, he died from exhaustion, comfortably, in quietude, and without distress. Now, if you think for a moment, if by chance any of you happen to have seen a man dying from intestinal obstruction, of the contrast between one dying in the way that this man did and the way in which people similarly circumstanced generally die—the stinking vomit coming from the mouth and nose and creating a horrible disgust which is quite indescribable—you will see at least that if in this particular instance the treatment did not finally save the patient's life, it certainly prolonged it and insured a peaceful end—a matter of no small moment.

---

[1] On Vomiting, considered from some of its surgical aspects, especially with reference to a fæculent vomit which is sometimes curative, Brit. Med. Jour., March 24th, 1900.

[2] When really stercoraceous, vomiting is in itself occasionally curative: see address above referred to.

[3] In order to economise space some purely elementary points appropriately included in the lecture as delivered are omitted here.—W. H. B.

Case 2.—The next case is even more instructive. The patient was a man in the FitzWilliam ward, about 45 years of age, who had a very large irreducible hernia, which proved at the operation to be for the greater part omental. The amount of omentum which had to be removed, as it was almost all adherent, was very large, weighing something like a pound, and, as I have often pointed out here and elsewhere,[4] when large masses of recent, that is to say, normal, omentum are ligatured, you are liable to find symptoms arise during the first 48 hours after the operation which are indistinguishable from those of strangulation of the bowel, and in cases of this kind, in which a hernia has been operated upon, I have known the wound to be opened up. In fact, the abdomen has been opened on the supposition that there has been recurrent strangulation when the symptoms were simply due to a tightly ligatured omental mass which, if left alone, generally ceases to cause irritation and the patient as a rule gets well. In this particular instance these symptoms followed and they were, I think, the worst of the kind I have ever seen, because within 48 hours of the operation the abdomen was distended to a great degree and there was vomiting of material which my house surgeon called stercoraceous and which certainly was stinking and very offensive whilst the patient looked like a man who was dying. He had, up to the time of my seeing him, which was about 24 hours after the onset of these symptoms, been treated in the orthodox manner to which I have referred. As soon as I saw him in this condition I ordered him to have any amount of water to drink. He very soon took advantage of the permission and drank large quantities, as patients suffering in this way do, although they vomit at first almost as soon as the fluid passes into the stomach. The result was, as in the case which I have already described, that very rapidly the stinking character of the vomit disappeared and there was simply ejected from the stomach at intervals clear water without effort and without discomfort. An almost immediate change in the patient's aspect commenced to show itself and, after a free action of the bowels, which could not previously be brought about, had been obtained by the use of enemata, he recovered. I believe I am right in saying that there is not the least doubt that had the orthodox treatment been here used this man would have died, and died very shortly, from the effect of this fœtid vomiting occurring in the manner in which it does in such cases. That is an example, then, in which a departure from the orthodox treatment, I have no doubt, saved the patient's life.

Case 3.—The same result followed in this instance, the patient being a child, aged 13 years, upon whom I operated for appendicitis—a subacute appendicitis of the worst kind, one of the most difficult operations I have had to perform, I think, for the removal of the appendix; in fact, it was a question at one time whether it would not be wiser to give up the attempt. We persevered, however, and finally removed the diseased mass, hoping that things would go well. Precisely the same state of affairs occurred in this child within 12 hours of the operation as happened in the foregoing case of the man. No doubt the child developed peritonitis, which was not remarkable considering the difficulties of the case, there having been an abscess as well as some sloughing tissue to be dealt with. The vomiting came on in the same way as in the other cases and all the child begged was that she might have something to quench her—thirst—the universal cry of all these patients. Fortified by my previous experience I gave the child as much water as she cared to take; and she took it by the pint. The same sequence of events followed. The vomit cleared, the attempts at vomiting were quite effortless, the ejection became nothing more than a mechanical regurgitation, the distressed look on the face disappeared in a few hours, and the child recovered, which I do not believe for a moment she would have done if she had been treated on the orthodox principle.

Case 4.—This is another equally striking example. A middle-aged man, of a strongly alcoholic temperament, received a blow upon the abdomen which caused slight discomfort only at the moment. On the following day "cramps in the stomach" began to occur with distressing and increasing frequency. Vomiting soon set in and before long assumed the stinking type. The abdomen became distended and tender and the aspect of the case seemed grave. Operative measures were considered but were declined on the ground that recovery could not be guaranteed. Under the orthodox treatment by deprivation of fluid by the mouth the thirst became intense and the patient seemed to be rapidly getting exhausted. Free libations of cold water upon the lines indicated were taken. The vomit quickly became clear and inoffensive, the thirst disappeared, the foully coated tongue cleaned, whilst the patient's general condition improved with singular steadiness. For 24 hours vomiting of clear water followed the free libations and then by degrees passed off. I have no doubt that the plan adopted saved the patient's life. What the pathological condition present was I cannot say, but it had all the clinical characters of peritonitis.

These four cases suffice, although I could quote others, to show the advantage of adopting the plan which I advise you to use in the circumstances. Of course, in doing so it must be remembered that you are running counter to the orthodox teachings, you must therefore be prepared to have exception taken to the method. But if by adopting a method of this kind you are merely able to make a dying patient more comfortable by relieving the terrible thirst as well as the distress and disgust which are engendered by this vomiting, that in itself is sufficient to justify your attitude. And further, if it is possible, as I have not the least doubt it is, as I have been able to show in some of the cases which I have mentioned, actually to save life by the proceeding, a departure from the ancient method is not only fully justified but becomes a mere matter of duty under the conditions which I have described.

Plumbing in Relation to Health.—One of the most important factors in domestic hygiene is the avoidance of structural defects in the dwelling house. These may be of many kinds but the most serious are deficient admission of air and light, dampness, and improper or defective drainage. With the modern system of water carriage of excreta the entrance of sewer air into a house is an evil to be dreaded and for its exclusion the householder must rely almost entirely on the goodness of the plumber's work. In an address delivered on May 30th at a public meeting in Bristol on Plumbing in Relation to Health Dr. D. S. Davies, medical officer of health of the city, said that 20 years ago it was often assumed that drainage defects were responsible for the spread of the majority of the communicable fevers. Later experience had modified that view and had reduced the number of specific diseases capable of propagation in this way, but it was none the less true that grave injury to the general health resulted from inattention or ignorance in carrying out the practical details of plumbing work. The registration of plumbers was therefore desirable and there was great need for able, careful, and guaranteed workmanship.

[4] Clinical Lectures on Abdominal Hernia.

N ANALYSIS OF 300 CONSECUTIVE GYNÆCOLOGICAL LAPAROTOMIES.[1]

RTHUR H. N. LEWERS, M.D. LOND., F.R.C.P. LOND.,

OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

PART I.

HE cases dealt with in this paper are all the cases of ominal section performed by me between April 3rd, 1901, Oct. 14th, 1904. They extend, therefore, over a period hree years and six months, but may be more correctly rred to a period of three years and four months, as the e of the penultimate case in the list is August 12th, 1904, r which I was away for two months. Allowing for idays in the other years the cases may be considered with e approach to accuracy as representing three years' work n average of 100 cases a year. The cases, however, are evenly distributed over the period of time under review. ce June, 1903, when I succeeded to the senior post in my artment at the London Hospital, down to the date of the th case in the list (Oct. 14th, 1904), I performed lominal section 160 times, thus leaving only 140 cases onging to the previous two years.

he cases are tabulated consecutively in chronological ler as they occurred. The plan that has usually been opted of publishing separately a large series of ovariomies, abdominal hysterectomies for fibroids, and so on, pears open to criticism. It is apt to lead to the exclusion most of the fatal cases; at all events it would have had is effect if applied to the present series. In classifying e cases in my table I have several times been struck with e difficulty of deciding into which class a particular case ould go. No doubt in the majority of the cases it is easy come to a right decision. An ovariotomy, of course, goes to the list of ovariotomies and an abdominal hysterectomy r fibroids into the list of cases with that heading. But hat is to be done when a case occurs in which both these perations have been performed at the same time on the ame patient? In operations for the removal of the uterine ppendages the same difficulty occurs. Not rarely on one ide or the other the ovary shows more or less definitely ystic degeneration. Suppose there is single or double yosalpinx present and that on one side there is a cystic vary, for example, of the size of an orange, how should the peration be classified? Is it an ovariotomy or an operation or the removal of inflamed appendages? It is scarcely fair o call it an ovariotomy since nearly all the danger of the peration is due to the condition of the tubes. Without welling further on this point I think most of us will agree that, as regards gynæcological work, the only satisfactory course is for an operator to publish his cases of abdominal section in consecutive series as they occurred, and at the same time to publish a sufficiently large number to eliminate the chance that a particular run of cases may have happened to be unusually favourable.

The cases in my paper are classified under the following groups. 1. *Ovariotomy*.—By this is meant the complete removal of an ovarian tumour, cystic or solid, and in this group are included operations for the removal of cysts of the broad ligament and tubo-ovarian cysts. Cases in which hysterectomy for any reason has been performed are placed in a separate category. 2. *Abdominal hysterectomy for fibroids, including panhysterectomy*.—In the great majority of the operations for fibroids the operation adopted was the supravaginal amputation of the body of the uterus, leaving more or less of the cervix as a stump. Cases in which an ovarian tumour has been removed at the same time have been placed in this class. 3. *Removal of inflamed uterine appendages*.—In this group are placed the cases in which the pathological condition of the Fallopian tubes appeared to be the chief morbid factor present. This group includes cases in which a more or less definitely cystic ovary was removed as well as the diseased tubes. 4. *Abdominal section for ectopic pregnancy*. 5. *Abdominal hysterectomy for conditions other than fibroids*.—In this group are included cases where the uterus has been removed for hæmatometra, carcinoma of the body of the uterus, or as an incident in an ovariotomy or operation for pyosalpinx. 6. *Exploratory laparotomy*. 7. *Cæsarean section*.—Some objection may be made to including these cases in a list of gynæcological abdominal sections. But, to make the list of cases in which I have opened the abdomen during a particular period strictly consecutive, I have thought it better to include cases of Cæsarean section, as well as laparotomies for ectopic pregnancy, to the inclusion of which similar objections apply. 8. *Myomectomy*. 9. *Hysteropexy*.

I. *Ovariotomy*.—An analysis of the cases here tabulated shows that there were exactly 100 ovariotomies in the 300 cases under consideration, a fact of which I may say I was unaware till the analysis was made. Among these 100 ovariotomies there was no mortality, nor any incomplete operation. The numbers of these cases in the table are.: 1, 3. 4, 8. 10, 14, 26, 30, 32, 33, 42. 43, 45, 52, 55, 59. 60 66, 69. 70. 73, 78. 80, 82, 84, 95 96, 99, 105, 114, 115, 116, 118, 119, 124, 129, 131, 132, 133. 135, 137. 138, 140, 145, 146, 157, 159, 170, 171, 173, 175. 179. 181, 182, 184, 192, 196, 200. 201. 202, 203, 206. 210, 215, 217, 219, 221, 225, 229, 2 0, 231, 232. 233, 239. 243, 244, 245, 249, 250, 254, 255, 257, 261. 262, 264, 268. 269, 273, 274, 275, 276, 277, 285. 2, 288, 293, 294, 296. 297, and 298 = 100. In 29 of these cases the disease was bilateral (Nos. 8, 14, 30, 32, 45, 5 60, 78. 95. 96, 105, 115, 131, 135, 138, 140, 145, 157, 59, 175, 192. 196, 206, 215, 217, 261, 273, 274. and 29). The pedicle was twisted in 18 cases (No. 43. 59 69, 0, 78, 82, 116, 131, 145. 173, 184, 192. 219. 245, 255, 27, 293. and 296). The cyst was suppurating in nine cases (os. 14, 124. 146, 203, 210, 239, 244. 268, and 275). In one case (No. 30) there was a double uterus. In one case (No 55) the patient had a carotid aneurysm. In seven cas the tumour was a dermoid (Nos. 69, 140, 202, 225, 2, 232, and 274). Enucleation was required in ten cases (os. 73, 105, 118, 119. 124, 135, 159, 171, 181, and 250). three cases (Nos. 82, 184, and 261) the patient was pregn t at the time of the operation; in two of these a miscarria occurred soon afterwards. In one of these cases (No. 2) it is interesting to note that both ovaries were cystic, ming tumours of the size of a child's head one year old. he patient was four and a half months pregnant at the tim f the operation and it was only 13 months since her last nfinement at term. In two cases (Nos. 129 and 179) t ovarian tumour was a fibroid. The ureter was seen in th course of separating the cyst in seven cases (Nos. 135, 1 181, 244, 250, 275. and 285). In one case (No. 275) the eration was to remove the rest of an ovarian tumour left y another operator four years previously. Drainage was nployed in nine cases (Nos. 1, 73, 105, 118, 137, 239, 25 268, and 275). In one case (No. 1) Keith's tube was us and in all the others drainage by gauze was adopted.

II. *Abdominal hysterect y for fibroids*—In this class there are 73 cases with fo deaths, a mortality of 5·4 per cent. In two of the fata ses death was due to intestinal obstruction—in one of the (No. 40) caused by a coil of small intestine adhering to e seam across the floor of the pelvis; in the other case (N 51) caused by a coil of intestine passing through a hole in omentum about a month after the operation. As these the only cases of abdominal section in which intestina bstruction has occurred in the whole of my experience, th cident must be a very rare one. I think, however, that *a pri* there is more risk of it after abdominal hysterectomy fo roids than in other gynæcological laparotomies. The rem l of the uterus obviously leaves a vacancy in the pelvis tha es not occur after ovariotomy, so that intestine must ne arily more readily occupy the pelvis after hysterectomy. obably, however, this factor is not the only one, and the dent is more likely when there is a specially long mesente Since the occurrence of these two cases I always try to d the omentum down over the intestines, so as to have, if sible, the omentum intervening between them and the sea ver the stump. At the same time apertures in the omen can be recognised and closed. In one case (No. 58) death due to shock in three days' time in an extremely anæmic wo, aged 51 years. This patient had for some years been sed against operation but she had continued to grow wea and weaker till finally it was felt that operation was he y chance. This case, in fact, indicates what may be ca the mortality of expectant treatment. She ought to been operated on before her condition became so unfa able. In one case (No. 166) one part of the growth ha tended under the peritoneum, raising it from the left ilia a, so that extensive enucleation was necessary. This ient died from sepsis due, I

* R = recovery.

think, to infection from the rectum or sigmoid flexure, which had been laid bare in parts. The numbers of the 73 cases in the accompanying table are 5, 9, 13, 15, 17, 20, 22, 27, 31, 37, 40, 41, 46, 47, 53, 58, 61, 62, 64, 71, 77, 81, 87, 97, 98, 106, 109, 123, 126, 127, 128, 130, 136, 141, 142, 143, 144, 147, 148, 150, 152, 154, 160, 162, 163, 166, 168, 169, 180, 190, 194, 204, 212, 214, 222, 223, 224, 226, 240, 241, 246, 259, 260, 266, 270, 278, 283, 284, 286, 289, 291, 292, and 295.

III. *Removal of the uterine appendages for chronic inflammation.*—In this group there are 47 cases with four deaths. 15 of the 47 were cases of pyosalpinx. The four fatal cases were all cases of pyosalpinx. In the table the 47 cases are Nos. 2, 7, 11, 25, 28, 34, 36, 38, 39, 50, 51, 65, 67, 72, 74, 75, 76, 85, 88, 90, 93, 101, 102, 103, 104, 110, 111, 121, 125, 151, 155, 167, 177, 178, 183, 186, 187, 191, 195, 205, 213, 227, 248, 256, 265, 282, and 299.

IV. *Laparotomy for ectopic pregnancy.*—There are 33 cases of this kind in my list, with a mortality of one. Seven were emergency operations and in four of these the patient was so collapsed that intravenous injection of salt solution was employed as the abdominal section was begun. These all recovered. In three of the cases (Nos. 164, 235, and 237) the patient had been previously operated on for the same condition on the opposite side. The case that died (No. 29) was a patient suffering from peritonitis with a high temperature at the time of the operation. I used an iodoform gauze drain, which I now think was unnecessary, and it may indeed have had something to do with the fatal result. I never drain these cases now. The 33 cases in the table are Nos. 16, 19, 29, 35, 44, 49, 57, 83, 91, 94, 100, 108, 112, 134, 149, 161, 164, 172, 185, 189, 199, 211, 216, 220, 234, 235, 237, 242, 247, 252, 253, 271, and 281.

V. *Abdominal hysterectomy for conditions other than fibroids.*—There are 17 cases in this class. The numbers in the table are 6, 18, 23, 24, 54, 56, 68, 79, 86, 92, 113, 139, 156, 174, 188, 193, and 236. Six of these patients died. No. 6 was an emergency abdominal hysterectomy for hæmatometra on account of hæmorrhage during an attempt to evacuate the retained blood per vaginam. No. 54 was an abdominal hysterectomy for carcinoma of the body of the uterus in a patient, aged 62, with chronic Bright's disease, bronchitis, and emphysema. The patient was very stout and on account of the state of her chest could not lie down. Th wound ultimately broke down in its entire extent and th patient died a month after the operation. No. 86 was a abdominal panhysterectomy for carcinoma of the body o the uterus in a feeble patient, 63 years of age. She died fro embolism on the fourth day. No. 188.—In this case ther was a malignant mass growing from the peritoneal surfac of the uterus with secondary infiltration of the broad ligaments and hydroperitoneum. No. 193 was a case in whic hysterectomy became necessary during an operation fo removal of a pyosalpinx. No. 236 was a case of carcinoma of the body of the uterus in which a prolonged attempt was first made to remove the uterus by vaginal hysterectomy. As this proved impossible abdominal hysterectomy was performed as an emergency operation

VI. *Exploratory laparotomies.*—There are 14 cases of this kind in the table with a mortality of five. In seven (Nos. 12, 21, 122, 208, 267, 290, and 300) the condition found was malignant. Two of these patients died. There was one case (No. 107) which proved to be intestinal obstruction, one case (No. 158) of large old fæcal concretion which had caused enormous chronic dilatation of the sigmoid flexure, and one case (No. 280) where an operation was undertaken for an abdominal sinus freely discharging pus. These three patients died. There was one case of appendicitis (No. 207); one case in which adhesions about the tubes and ovaries were separated and hysteropexy performed (No. 165); one case in which a calcified tumour, unconnected with the uterus or ovaries, was removed from Douglas's pouch (No. 263); and one case in which pus was let out after separating intestinal and omental adhesions (No. 120); these patients all recovered.

VII. *Cæsarean section.*—There are eight cases of this operation in my list; only one (No. 218) proving fatal, a neglected case in which, unknown to me, the patient had been in labour four days. In two cases the operation was for obstruction due to fibroids (Nos. 63 and 89). In six cases the operation was on account of contracted pelvis (Nos. 117, 153, 198, 218, 238, and 258). Three of the patients were in labour at the time of the operation. Five were operated on before labour had commenced.

VIII. *Myomectomy.*—There are only three cases of this operation in my list (Nos. 48, 197, and 279). In No. 48 the patient was five months pregnant at the time of the operation. The pregnancy was not interrupted. In No. 197 there was a subperitoneal fibroid with a twisted pedicle, and in No. 279 there was a subperitoneal fibroid weighing 12 pounds with extensive adhesions (about 12 inches) to small intestine and mesentery. These patients all recovered.

IX. *Hysteropexy.*—There are five cases of this operation in the list—Nos. 176, 209, 228, 251, and 272, all of which recovered.

Summary.

—	Number of cases.	Number of deaths.
I. Ovariotomy	100	0
II. Abdominal hysterectomy for fibroids, including panhysterectomy for fibroids ...	73	4
III. Removal of uterine appendages for chronic inflammation	47	4
IV. Laparotomy for ectopic pregnancy ...	33	1
V. Abdominal hysterectomy for conditions other than fibroids	17	6
VI. Exploratory laparotomy	14	5
VII. Cæsarean section	8	1
VIII. Myomectomy	3	0
IX. Hysteropexy	5	0
Totals	300	21

That is to say, there was a mortality over the whole series of 300 cases of exactly 7 per cent. The series is strictly consecutive. It includes every case in which for whatever reason I have opened the abdomen during the period under consideration. Nor did I refuse to operate on any case because the operation seemed likely to be especially difficult or dangerous. This will, I think, be abundantly clear on an inspection of the particulars of the cases given in the table. I therefore regard the death-rate as being nearly if not quite as low as it should be.

It will be found that the cases of ovariotomy, ot abdominal hysterectomy for fibroids, of removal of the uterine appendages for chronic inflammation, of laparotomy for ectopic pregnancy, of Cæsarean section, of myomectomy, and of hysteropexy are 269 in number. These groups (I., II., III., IV., VII., VIII., and IX.) comprise by far the largest proportion of the abdominal sections that come under the care of the gynæcologist. In these 269 operations there were ten deaths, a general mortality for the groups in question of 3·7 per cent

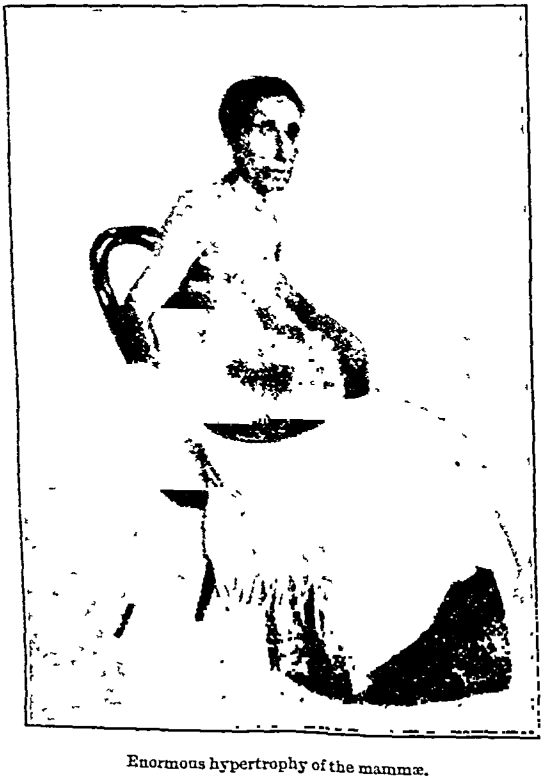
Remarks upon all these cases, which formed part of the tables when the paper was read before the Medical Society of London, will be published in the concluding part.

(To be concluded.)

A CASE OF HYPERTROPHY OF THE MAMMARY GLANDS.

By Dr. JAIME DARQUIER,
SENIOR PHYSICIAN, PIROVANO HOSPITAL, BUENOS AYRES.

The patient, a woman, 35 years of age, came to the hospital complaining of the trouble that the great enlarge-ent of the mammæ gave her, stating that the illness com-enced about 18 months before, the right breast swelling st and soon after the other. The increase was slow, ithout any pain, and her general state was normal. The xamination of the patient showed that all the organs ere healthy but the mammæ were enormously increased in ize, hanging down like saddle bags and reaching the umbilical line. The transverse diameter of the right, the larger, was 46 centimetres and its circumference 94. The nipple was completely gone and there were abrasions due to friction. The skin was very thick but not adherent to the deeper layers and the structure had the consistency of a normal breast; in the axilla of the same side there were three or four hypertrophied glands. The left breast was smaller than the right, its diameter being 42 centimetres and its circumference 85 centimetres; there were no abrasions, but as on the right side a few glands were found in the axilla, but smaller. So as to form an idea of the volume of the mammæ they were submerged into water, the right displacing 15 litres and the left 11 litres. Four grammes of iodide of potassium per day and compression of the breast were prescribed, but as at the end of two weeks there was no improvement to be seen it was decided to operate on her right breast, the operation being in charge of Dr. Emina. It was successfully performed by the usual methods, the glands in the axilla being also removed; the actual weight of the breast proved to be 13 kilogrammes. In the operation, which the patient endured very well, about a litre of blood was lost. The left breast at once decreased somewhat in size, but as it still continued to trouble the patient she asked that it should also be removed. This second operation was performed about a month after the first with the same good results; the actual weight of this breast was 10 kilogrammes. One month after this second operation the patient left the hospital completely recovered.



Enormous hypertrophy of the mammæ.

The microscopical examination by Dr. Fernandez showed that the tissue was formed of fibrous meshes with few cells and a good amount of vessels with thick fibrous walls. The glandular acini were atrophied by compression and only a few surrounded by fibrous tissue were healthy. The pathological diagnosis was as follows: chronic fibrous mammitis (Delbet), and diffuse fibroma of the mammæ (Duplay).

The majority of authors place this condition among the mild tumours of the breast but Delbet takes exception to this and classifies it as an acquired anomaly closely connected with the physiological development of the organ. In Dr. Puech's table the weight of such breasts varies from 4 to 15 kilogrammes. In a case treated by Billroth one of the breasts measured 68 centimetres in circumference and the other 65 centimetres. Exceptionally, they may reach almost incredible weights, as in the case treated by Dr Durston, in which one of the breasts weighed 30 kilogrammes. Delbet states that the skin of the breast is not thickened or adherent to the neighbouring parts; other authors affirm that the skin gets thick and hard, this being so in our case. Authors also differ as to the constitution of the hypertrophied tissue; Duplay states that the predominant element is the connective tissue which by its development greatly modifies the glandular tissue, destroying its functions, and for this reason calls it diffuse fibroma of the mammæ. Delbet, as stated, opines that it is a simple hypertrophy and that the predominance of one or the other of the elements is only due to the structure of the gland at the time the illness begins. If this happens during puberty the connective tissue is predominant, if during pregnancy the glandular. In our case the microscopical examination showed a great predominance of the connective element with atrophy of the glandular tissue, perfectly in accord with Duplay. The genesis of this condition is not well known; Duplay states that it occurs generally in women between 30 and 40 years of age; Billroth says that it is observed in an earlier age, a short time after menstruation appears, this opinion being also shared by Delbet. The hypertrophy of the breast generally begins in a slow form, without pain, exceptionally in an acute way, with fever (acute hypertrophy of Fingerhut); the increase may occur very rapidly, in one night (Durston, Quenu). Generally one of the breasts is attacked first and acquires the greater size. With the development of the illness the breasts are deformed and hang down as saddle bags, as the accompanying illustration clearly shows.

The diagnosis is unmistakeable and although in the present case there were glands in the axilla the fact of both breasts being attacked at the time of the illness excludes the probability of the condition being one of cancer in the strict sense of the term. It should be noted, however, that the glandular infection in our case could be accounted for by the abrasions on the right side only, on the left there was no alteration of the skin. On the other hand, there was some connexion between the size of the glands and the hypertrophy; on the left side with less hypertrophy the glands were smaller and after being operated on the left glands decreased in size. It is worth mentioning that in cases of such hypertrophy pregnancy helps to augment it very much. It is true that the mammary hypertrophy may remain stationary, but cases may be fatal, death occurring by a sort of marasmus or by local complications, gangrene, large abscess, &c. The prognosis is always, therefore, serious, and the treatment, seeing the poor results of medicaments, if the volume of the hypertrophy is great, is to remove the organ, a course that has given such good results in the present instance.

Buenos Ayres.

A SPORADIC CASE OF CEREBRO-SPINAL MENINGITIS.

BY J. RUPERT COLLINS, M.D., B.CH. DUB.

INASMUCH as it is only from the aggregate of individual cases of any disease that we are able to arrive at a correct estimate of it as a pathological entity, it is perhaps well when any types occur of a disease which is but seldom seen that they should be recorded. For this reason I shall now try to describe faithfully and clearly a case of cerebro-spinal meningitis which has occurred in Cheltenham, the first example of the disease in this town.

The patient was a girl, aged 13 years, whose father keeps a shop in which home and foreign birds but no quadrupeds of any description form the stock-in-trade. She was a fair, well-developed girl of a good constitution and had never suffered from any illness beyond having at times slight rheumatic pains in her knees and ankles, for which, however, she had never seen a medical man. Intellectually she was unusually bright and had acted as a teacher's help at school. On Sunday, May 21st, she felt quite well and went to afternoon school and church as usual. After church she went to a friend's house to supper and then for the first time complained of intense cold and sat shivering over the fire. She refused cake and sweets when offered her but drank some tea. On her return home, as she complained of severe frontal headache and "feeling bad," her mother gave her a small dose of antifebrin. She went to bed and slept quietly until the morning. At 9 A.M. she was given some Epsom salts but refused her breakfast and again went to sleep. At 12 noon her mother found her lying unconscious on the bed, having passed urine and fæces under her. At 1 P.M I saw the girl and found her unconscious, lying upon her left side. Her face was very pale, the mouth was wide open, the tongue was dry and very foul, and the breath was extremely fœtid. The pupils were small and equal in size. The respirations were shallow, 48 to the minute; the pulse was weak, 98 in frequency; and the temperature was 104·4° F. There was no sign of any injury on the head or body nor could I find evidence of any local septic process whatever. A few hours later she passed a large motion containing numerous currants. At 6 P.M. the pulse and respiration were better but she was still unconscious. She now vomited what was apparently her Sunday's dinner in an undigested condition. At 10 P.M. she was partially conscious, very restless, answered when shouted at, but would then relapse into a state of quiet delirium. She complained of pain in her back and forehead and cried out when moved. No rash of any description was present. Bromide of potassium, ten grains three times a day, was now ordered her. On the 23rd the child was more conscious but very restless; the tongue was moist and white but not so foul as on the day before; marked retraction of the head was now present. A specimen of urine was obtained; it was clear and light coloured, its specific gravity was 1006, its reaction was acid, and it contained a trace of albumin but no sugar. Towards evening she became very restless and excitable, crying out frequently, "My head! my head!" said she was dying and asked for chloroform to end her misery. The pupils were small, the conjunctivæ were suffused, and photophobia was present. Kernig's sign was now elicited; the knee-jerks were absent. Herpes were beginning to appear on the upper lip and three or four livid coloured spots were observed scattered over the body. I regarded the case as one of cerebro-spinal meningitis and asked Dr. Kirkland to see the patient with me; this he very kindly did the same night and confirmed the diagnosis The result of the physical examination was briefly as follows: the chest movements were calm, the percussion note was normal, and the breath sounds were clear. The position of the apex beat and the extent of the cardiac dulness were normal. The heart sounds were healthy. The abdomen was retracted and free from any localised tenderness; there was no enlargement of the spleen. No enlarged glands could be found anywhere, nor any enlargements of the bones nor periosteal tenderness. There were no sores upon the body. One-eighth of a grain of morphine was given hypodermically at 11 P.M.; this quieted the patient until 2 A.M., when she again became restless and delirious. On the 24th the eruption of labial herpes had become much more extensive, forming a complete ring round the mouth and extending up on to her cheeks. Symmetrical crops of herpes had come out over both knees, both elbows, over each ilium, and a small patch in each axillary fold. A condition of opisthotonos had now developed. Dr. J. H. Garrett, medical officer of health, kindly saw the patient with me and agreed as to its nature. One-sixth of a grain of morphine was now given but did not produce much effect. The patient was put on the following medicine:—Potassium iodide, 5 grains; ammonium bromide, 10 grains; tincture of belladonna, 4 minims; syrup of orange, half a drachm; and chloroform water to make up half an ounce—to be taken four times a day in water. As her bowels had not moved mercury with chalk, 5 grains, was ordered, to be followed by an enema. The elbows and knees had now become so sore that they had to be kept bandaged. The patient passed a very restless night, shouting and moaning so as to be heard in the street. On the morning of the 25th an erythematous rash appeared over the body and limbs. Dr. Kirkland now gave the patient chloroform and under strict aseptic precautions I made a puncture between the third and fourth lumbar vertebræ. Immediately on passing the needle into the spinal canal a thick purulent-looking fluid welled up, about one cubic centimetre coming away; this was collected in a carefully sterilised test tube for subsequent investigation. At the same time cultures were made from the upper part of the nasal fossa by passing a sterilised platinum needle up to the superior turbinated bone and then inoculating directly tubes of Löffler's blood serum and of agar-agar. The anterior nares were quite dry and no visible secretion adhered to the needle on its withdrawal. Cultures were also taken in the same way from the pharynx. A leucocyte count by the Thoma-Zeiss hæmocytometer showed a leucocytosis of 15,887 per cubic millimetre. The patient now became easier and for some hours was quieter than she had been even after the administration of morphine. She also passed a better night than she had had since the beginning of her illness. On the next morning, the 26th, she for the first time recognised me as a medical man and did as she was asked. The head was still more retracted, however. She complained greatly of thirst, due no doubt in part to the belladonna, and drank large quantities of lemon water in addition to three pints of milk, beef-tea, and albumin water. There was never any difficulty in getting her to take abundance of nourishment. A scarlatiniform rash appeared and disappeared in the space of a few hours. She again had a very restless night. On the 27th she was more restless than ever, wanting to get out of bed, turning from one side to the other, and crying out with the pains in her back and forehead. One-sixth of a grain of morphine was given hypodermically but produced no effect at all. The livid-coloured spots noticed at the beginning of the illness had now disappeared but a small patch of petechiæ had formed on either side of the chest at the lower thoracic margin. On the 28th she was quieter and more sensible, the left side of her face was flattened, and the corner of the mouth on the right side was drawn up. The forehead and eyelids were unaffected. The tongue, which had become cleaner, when put out deviated to the left. An evanescent scarlatiniform rash was again present. A leucocyte count showed a leucocytosis of 13.569 per cubic millimetre. At 3 P.M. she fell into a deep sleep which continued unbroken until midnight, when she woke for a few minutes, had a drink, and went to sleep again until 6 A.M. the next morning, the 29th. When I came to see her at 11 A.M. she of her own accord told me that she was much better. The retraction of the head was less and she seemed to be very decidedly improved. The urine when examined was of specific gravity 1008, the reaction was neutral, it contained no albumin and no sugar. She passed a good night and on the 30th was becoming convalescent. Kernig's sign was now absent and the flattening of the face was less marked. On the 31st she was allowed solid food; the tongue was now quite clean. A slight patellar reflex was elicited; pain and headache had ceased and she was able to bring the head into a line with the body but could not flex the neck beyond the vertical. All that remained of her illness was some stiffness of the back and inability to flex the neck, with some paresis of the lower part of the face. With an effort she could now manage to whistle. (Fig. 1)

The patient's mental state throughout the illness impressed me so forcibly that I recapitulate it here in greater detail.

After the initial unconsciousness had passed off she would continue to talk away, uttering at times nonsense, but generally disconnected fragments of conversation relating to her ordinary life, such as shopping, saying her lessons, &c. If spoken to she showed the greatest irritability and at times became violently excited, especially if the nurse or myself persisted in doing anything she disliked. Any loud sound annoyed her greatly. The prick of the hypodermic needle always gave rise to the most bitter reproaches, sometimes mingled with threats and sobs. There seemed to be no dulling whatever of the sensorium; she remembered exactly the number of times I had pricked her with the needle and kept accurate count of the days of her illness. The pains were apparently of the most acute nature, wringing from her frequent moanings and complaints of her head and back, mingled with repeated appeals to me to give her chloroform and let her die and expressions of hope that she would not live long. She always referred the worst pain to the back and forehead and asked for, and apparently found relief from, the application of eau de Cologne on a handkerchief to the temples. Whereas most patients with this disease complain chiefly of occipital headache this was not so in her case. She complained also of pains in her abdomen and "all over." It seemed to be intolerable to her to remain in one position for any length of time, notwithstanding the fact that any movement gave her pain. Her mode of altering her position was curious. She would slowly raise herself on her hands and knees and keeping the head drawn stiffly back turn over to the other side, to which she would arrive with apparent relief, but only in a few minutes to change to a fresh posture. The attitudes are depicted in the accompanying illustrations. (Figs. 2 and 3.) At times she apparently found relief in lying upon her abdomen and resting her chin upon the pillow. As a rule she preferred turning herself to being helped by another, owing to the ever-present dread of her head being moved. If help were given she kept crying incessantly "Mind my head, mind my back." Her attitude with the head drawn back between the shoulders, and arms and legs as a rule flexed, her constant restlessness in spite of the pain she thereby occasioned herself, her delirium and fractiousness, her general hyperæsthesia of the skin, all combined to indicate a widespread superficial irritation of the brain and spinal cord. Superficial because, with the exception of the cervical retraction, there was no definite localised spastic or paraplegic condition of any particular group of muscles or lesion of any particular sense such as would result from a deep-seated pathological focus.

Course of temperature.

The bacteriological examination proved the case to be due to the presence of the diplococcus intracellularis meningitidis of Weichselbaum. Cover-glass preparations of the cerebro-spinal fluid were made immediately after its removal and were fixed in equal parts of alcohol and ether. These exhibited large numbers of leucocytes, mostly polymorphonuclear and large mononuclear cells, a few degenerated but the great majority intact with a clearly defined nucleus. Diplococci, few in number, were found, both intra- and extra-cellular; none were observed within the nuclei. These diplococci were decolourised by Gram's method and took up the counter-stain bismarck brown; they were so few in number that it took an hour's search to find any. Cultures were made from the cerebro-spinal fluid in broth, on Löffler's blood serum, and on agar-agar. In 48 hours a growth appeared in the tubes of broth, forming a small white deposit at the bottom but leaving the broth itself clear. When shaken this deposit eddied up like a stringy substance attached by one end to the bottom of the test tube. On Löffler's blood serum an almost colourless growth, flat, confluent, and seen with difficulty, developed. The tubes of agar-agar exhibited no growth at all. Tubes of agar-agar were now inoculated from the growth on the blood serum; in 24 hours translucent colourless colonies, discrete and elevated, appeared upon the agar-agar, its passage through the Löffler's blood serum having apparently increased its hardiness. All these growths were pure cultures of a diplococcus decolourised by Gram's method but staining well with the ordinary aniline dyes. The confronting sides of the diplococcus were flattened and it frequently occurred in tetrads. The individual cocci showed variations in size and also in depth of staining, this being especially well seen when stained with bismarck brown. In a tetrad sometimes three would be

FIG. 2.

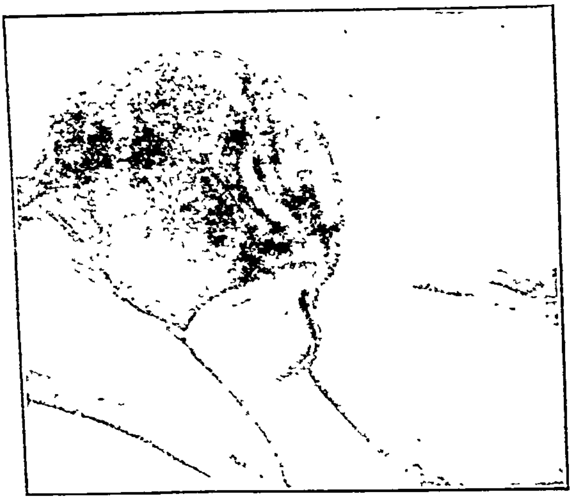
FIG. 3.



Patient lying on face.

lightly stained and the fourth coccus stained deeply. Examples of both the lightest and deepest stained cocci were, as a rule, found amongst the larger forms. The component cocci of a single diplococcus were not infrequently unequal in size.

The cerebro-spinal fluid itself was kept for 48 hours without any noticeable increase in the number of diplococci. It was then incubated for 24 hours at 39° C. and proved an excellent pabulum for the organism which grew luxuriantly in it. This is, I think, of some importance, apart from its interest, as cases may occur where suitable culture media are not obtainable. Of the tubes inoculated from the nasal cavity, mixed growths developed both on the agar-agar and on the blood serum. No growth of the specific organism could be found upon the agar-agar, but on the Löffler's blood serum colonies of the diplococci were obtained. No growths of the diplococcus were discovered in the cultures made from the pharynx. The urine immediately after being voided was centifuged; the deposit was washed in distilled water, re-centrifuged, and examined; but though numerous micro-organisms, including diplococci, were found none were detected exhibiting the characteristics of Weichselbaum's diplococcus. The cerebro-spinal fluid was tested as to the presence of iodide of potassium but was found to contain none; ten grains of it had been taken when the lumbar puncture was made.

As to how this case occurred I can offer no explanation. The presence of the organism in the nasal chamber would point to an aerial infection. There was no history of letters, books, clothes, animals, or friends coming from a distance, nor had the child been away from Cheltenham.

I would like to express here my obligations to Dr. Kirkland, not only for his help and interest in the management of the case but also for his kindly assistance in preparing this account of it.

July 1st.—The patient has continued to make an uninterrupted recovery and is now perfectly well.

Cheltenham.

A CASE OF PERFORATED GASTRIC ULCER WITH FATAL HÆMORRHAGE FROM THE BOWEL IN AN INFANT 45 HOURS OLD.

By A. GRAINGER BISSET, M.B., Ch.B. Glasg.,
LATE HOUSE SURGEON TO THE VICTORIA INFIRMARY, GLASGOW.

I was hastily summoned one evening to see an infant who was said to be bleeding profusely from the bowel. The mother had been delivered at 4 A.M. the previous day by a midwife who stated that the confinement was in every way normal, the entire duration of the labour (the ninth) not exceeding three hours. When I saw the infant, a boy, he was lying in a semi-collapsed state. The mother's story was that in the evening the child had refused the breast altogether, although he had previously taken it quite readily. When she proceeded to change the infant's napkin, about 7 o'clock, she found that it was saturated with blood of a slightly dark colour and while she was preparing a fresh napkin two great gushes of blood spurted out from the child. On removing this second napkin I found it soaking with blood and a little still continued to ooze away from the anus. The bowels had previously been moved naturally, the colour of the stools being that of meconium. There was no sign of prolapse. The umbilical cord had not been tied until pulsation had ceased; it was properly secured and looked perfectly healthy. There was no history of hæmophilia, syphilis, or phthisis, and the child was not jaundiced. The heart-beats were regular; there was no bleeding from the mucous membranes and nothing to suggest that the child had swallowed blood—e.g., from fissured nipples, or during the act of birth. On examining with the finger in the rectum and bimanually nothing abnormal could be detected; the finger on withdrawal was covered with blood of a fresh colour. The abdomen was most carefully palpated without revealing anything unusual; no tenderness, localised or general, seemed to be present. Invagination of part of the bowel was thought of as a possible cause of the hæmorrhage, but the great quantity of blood lost, its non-admixture with mucus and slimy matter, together with the absence of blood-stained motions and of any indication of tenesmus seemed to negative that view; nor were there any physical signs to support it. Gastric or duodenal ulcer appeared to be excluded by the entire absence of vomiting and by the comparatively fresh colour of the blood lost. A provisional diagnosis was made of some form of ulcer pretty low down in the intestine as being the likeliest cause of the hæmorrhage, and, acting on this theory, a rectal injection of equal parts of adrenalin and hamamelis was given, the grave condition of the child precluding any possible surgical measures being resorted to. A small plug of cotton-wool was inserted temporarily in the rectum to retain the injection. The infant was then placed in bed with the legs raised and the head lowered. A very bad prognosis was given, having regard to the large amount of blood lost, and this was amply justified by the infant's death three hours later, being six hours after the bleeding was first noticed and 45 hours after birth.

Necropsy.—Post-mortem examination was restricted to the contents of the abdomen. On opening into the abdomen no blood was found in the peritoneal cavity. The entire length of the intestine was examined for intussusception but none existed. The whole alimentary tract was then removed in one piece from above the cardiac opening of the stomach to the lower rectum and was slit open along its entire length when it was seen to be filled with blood, mostly in a semi-fluid condition. No indication of ulceration was found until the stomach was reached. This organ contained a large amount of semi-fluid blood and mucus mixed with partially digested milk. On carefully washing away this detritus a typical gastric ulcer of the acute form was exposed, with perfectly clean-cut, punched-out margins, situated on the posterior wall of the viscus near the lesser curvature and about half an inch from the cardiac opening. The ulcer was completely perforated and, as some shreds of mucoid material were found adhering to its peritoneal aspect, the posterior abdominal wall was again examined and a little of this blood-stained mucoid matter was seen lying in the situation which the ulcer must most probably have occupied, evidently indicating that adhesion of the ulcer had actually taken place at this point but had become separated during the removal of the stomach from the abdomen and had been the means of preventing the escape of the blood into the peritoneal cavity. The ulcer was circular in form and was almost of the size of a threepenny-piece on its inner surface. Running up to the ulcer a blood-vessel could be traced with some difficulty, probably a large branch of the left superior coronary artery of the stomach and the one whose rupture had set up the hæmorrhage. The mucous lining of the stomach for a radius of three-quarters of an inch from the circumference of the ulcer was markedly congested and formed a notable contrast with the remainder of the mucosa which was distinctly paler in colour. There was a slight thickening all round the edges of the ulcer and its immediate vicinity. The other abdominal organs were normal.

Gastric ulcer is very rare before puberty, yet it has occasionally been observed soon after birth and also in the newly born. In most cases it has been the simple ulcer but tuberculous and syphilitic ulcers have been described in this connexion. The extreme rarity of the condition in the very young has been attested by various writers. Thus Fenwick[1] refers to 18 collected cases of genuine examples of ulcer of the stomach in infancy or childhood, 13 of which were of the acute type and five of the chronic variety, the ratio of females to males being 4 to 1. Welch,[2] quoted by Fenwick, found out of 607 cases only one case occurring in the first decade of life, and Rokitanski[3] had not met with a single case under 14 years of age in his extensive experience. Goodhart[4] records a case in which death took place 30 hours after birth and in which the ruptured vessel could be seen with a lens lying open in the floor of the ulcer. Ulceration of the stomach at birth has also been described by Rilliet, Billard, Henoch, Dreschfeld, Düsser, and others. Recently Morris and Feldman[5] have published a case of hæmatemesis and melæna in an infant two days old, due undoubtedly to gastric ulcer, in which recovery took place, a termination met with, according to Eichhorst, in less than 50 per cent. of such cases. Actual perforation of the ulcer, as in our own case, is extremely rare. A puzzling feature of this case was the entire absence of vomiting. Considering the ease with which infants reject the contents of the stomach it certainly seems strange that all the blood should have been passed per rectum. In most cases of gastric ulcer blood accumulating in the stomach acts as a foreign body and excites nausea, followed by vomiting in a very short time. In other cases, again, the irritation of blood lying in the stomach would seem to stimulate intestinal movements to get rid of it by the bowels. Still, it must be very rare that vomiting is entirely absent and that all the blood is voided per rectum. Such a condition would almost suggest *a priori* a mode of distinguishing between duodenal and gastric ulcer but this case seems to show that such a distinction cannot be depended on. What determined the actual onset of bleeding in the case is an interesting speculation. Most probably it was due to the milk imbibed setting up vigorous gastric peristalsis, which, with the concomitant increased vascularity of the organ consequent upon the act of digestion, would be sufficient to bring about the final rupture of the already partially eroded vessel or to dislodge any clots which may have sealed over the opening of the vessel at the point of erosion.

RATES OF ATTACK BY ENTERIC FEVER IN 90 LARGE TOWNS OF ENGLAND AND WALES.

By G. S. BUCHANAN, M.D. Lond.,
MEDICAL INSPECTOR OF THE LOCAL GOVERNMENT BOARD.

A GENERAL indication of the relative degree of prevalence of enteric fever in different towns, or groups of towns, in England and Wales can readily be obtained by reference to the mortality returns published by the Registrar-General. Often, however, it would be more useful to be able to contrast the relative number of notified cases of this disease than to be guided by the relative number of deaths. In an addendum to a report to the Local Government Board on the sanitary circumstances of Sheerness, lately published, I have recorded a considerable series of attack rates by enteric fever which were calculated for this purpose and are likely to be of sufficient general utility to warrant their reproduction.

In the table below are given the annual attack rates by enteric fever in 90 large towns of England and Wales during the years 1898 to 1904 inclusive. The middle year 1901 is the census year and the rates have in each instance been reckoned on the 1901 census population, a proceeding sufficiently exact for the purpose required. The figures have been extracted and tabulated in the medical department of the Local Government Board by Mr. W. Hunter. My colleague Dr. Theodore Thomson, in a report on enteric fever in Swinton and Pendlebury (Annual Report of the Medical Officer of the Local Government for 1898-99, p. 168) gave the annual attack rates by enteric fever of 50 towns for which the necessary data were then available. These figures were quoted at the time in THE LANCET.[1] For convenience of comparison I have marked these 50 towns with an asterisk in the table below. The annual attack rate by enteric fever for the whole of these 50 towns during the period with which Dr. Thomson dealt, 1893–97, was 1·03.

The table below gives the annual attack rates by enteric fever from 1898 to 1904, inclusive, of: (*a*) the 75 towns of England and Wales which had a population at the 1901 census exceeding 50,000. In the case of 35 of these 75 towns the corresponding attack rates for the period 1893–97 were given by Dr. Thomson in the report referred to. (*b*) 15 towns of England and Wales with a population at the last census less than 50,000, in respect of which Dr. Thomson gave the corresponding attack rates for the period 1893–97. The total number of towns dealt with in the table is thus 90. The data enable calculation of the following annual attack rates by enteric fever during 1898–1904: all the 90 towns, 0·96 per 1000; all the 75 towns of England and Wales whose population at the 1901 census exceeded 50,000, 0·97 per 1000; all the 50 towns whose attack rates for 1893 to 1897 were given by Dr. Thomson, 0·89 per 1000.

* Fifty urban districts for which attack-rates by enteric fever in 1893–97 were recorded by Dr. Thomson in the annual report of the Board's medical officer for 1898–99, p. 168.

[97], [93], &c. In the year indicated the number of enteric fever cases notified exceeded one quarter of the total number of enteric fever cases notified during the seven years 1898–1904.

---

[1] THE LANCET, Feb. 25th, 1899, p. 542.

A NOTE ON THE EXAMINATION OF CULTURES AND SMEARS FROM THE THROAT AND THE NOSE.

BY W. T. GORDON PUGH, M.D., B.S. LOND.,
SENIOR ASSISTANT MEDICAL OFFICER, NORTH-EASTERN HOSPITAL, METROPOLITAN ASYLUMS BOARD, LONDON.

IN relating a staining method which has been used for the detection of the bacillus diphtheriæ at the North-Eastern Hospital for about 18 months and which, so far as I can ascertain, has not been already described in this connexion, it may be well at the outset to intimate that no new feature of the bacillus is brought out and the sole reason for this note is that the stain has proved more convenient than others in general use. It is now customary to make several cultivations from the throat and nasal cavities of diphtheria convalescents before discharge from hospital in order that freedom from infection may be insured; in many hospitals, also, cases of scarlet fever are examined at the time of admission with a view to preventing the occurrence of post-scarlatinal diphtheria. *Examination for the bacillus diphtheriæ thus* occupies a prominent position in the routine work of a fever hospital and it is essential that the method adopted should be speedy and convenient. The reaction to litmus of subcultures in neutral glucose broth, pathogenicity to guinea-pigs, and appearance of colonies on various media are tests obviously not suitable for routine work and the question reduces itself practically to a consideration of the methods of staining films of colonies found in a blood-serum cultivation after some 20 hours' incubation.

For many years it has been recognised that the protoplasm of certain bacteria contains granules that stain deeply with aniline dyes. The significance of these granules, the so-called Babès-Ernst bodies, has not been definitely established. Some have believed them to be products of degeneration, while others, on the contrary, have regarded them as reserve substances. Ernst attributed a nuclear nature to them and Crouch[1] thought their polar position possibly represented a division of nuclear substance preliminary to the division of the micro-organism. These granules are especially well marked in diphtheria bacilli when grown for 20 hours on blood serum prepared according to Löffler's formula and in my experience they occur with remarkable constancy. It thus comes about that the differential staining of these Babès-Ernst bodies forms the basis of nearly all the staining methods for the recognition of the Klebs-Löffler bacillus. It must not be forgotten, however, that this bacillus is but one of several micro-organisms which show these granules, and it is well when the bacilli under observation do not conform in general appearance and arrangement with the recognised standard that they should be investigated in further detail. The final and only certain laboratory test for the bacillus diphtheriæ is that it is pathogenic to the guinea-pig, while a control animal protected by antitoxin is immune. Bacilli showing polar granules may sometimes be obtained from the throat, nares, and especially the ear, which are not pathogenic to the guinea-pig. One form so closely resembles the bacillus diphtheriæ in all its reactions as to be regarded as a non-virulent form of this organism; it appears to be not very uncommon in the throats and noses of healthy school-children in large centres of population where diphtheria is endemic, and there is no evidence that it can become pathogenic. There are occasionally found other non-virulent bacilli which, while showing polar bodies, generally differ from the Klebs-Löffler bacillus in length, arrangement, coherence, or rate of growth on blood serum sufficiently to make the risk of their being confounded with the more important organism not a great one. Mervyn Gordon[2] and Graham-Smith[3] have examined in detail a number of these bacilli, which are especially to be suspected in cultures from the ear, and their papers and illustrations may be consulted with advantage. Again, the bacillus *coryzæ* segmentosus, found in the nasal discharges in acute influenzal cold, may show polar granules in a small proportion of bacilli. The bacillus Hoffmanni usually exhibits none of these bodies, but occasional colonies, especially in cultures obtained from the nose, may show granules in scattered bacilli; these as a rule are readily differentiated by the shortness and uniformity of the individual micro-organisms. Similar granules may be present in leptothrix of the mouth, not infrequently seen in swab-smears, while some varieties of cocci and streptobacilli exhibit them markedly.

The procedure for demonstrating these polar bodies originally recommended by Ernst consisted in staining first with a methylene blue solution and then with vesuvin for a few seconds. Crouch[4] in 1895 used methyl green and dahlia, followed by vesuvin. In 1896 Neisser[5] introduced the use of a methylene blue solution, acidulated with glacial acetic acid, for one to three seconds, counterstaining with vesuvin for three to five seconds. In three out of 39 typical cultures of virulent diphtheria bacilli, however, he failed to show polar granules by this method,[6] and various slight modifications (principally as regards time) were later proposed by several observers.[7] Pitfield[8] (1901) used three solutions containing silver nitrate, pyrogallic acid, and carbol-fuchsin. Hunt's method also involved the use of three solutions—methylene blue, tannic acid, and methyl orange. M. Piorkowski[9] (1901) recommended Löffler's methylene blue, followed, after decolorisation with acid alcohol, by eosin. W. G. Schauffler,[10] his pupil, improved on this, using a mixture of Löffler's blue, acid alcohol, and pyronin; while Andrade[11] has published yet another stain, a mixture of Borrel's blue and vesuvin solution. Of these, Neisser's method has met with most popularity; it requires, however, some care and experience in its application for a negative result to be trustworthy. A course commonly adopted is to examine a film stained by Löffler's blue and to confirm by examination of a duplicate specimen stained by Neisser's solutions. The stain which I have used during the past 18 months combines to a great extent the advantages of these two methods. It consists of toluidine blue[12] (Grubler's, obtained from Baird and Tatlock, Hatton-garden) one gramme, dissolved in absolute alcohol 20 cubic centimetres and distilled water one litre, to which glacial acetic acid, 50 cubic centimetres, is added. The stain has been usually applied for two minutes, but it may be left on considerably longer without ill-effect. When examined in a bright artificial light all the Babès-Ernst bodies, whether in bacilli or cocci, are seen to be stained a reddish-purple, the diphtheria bacilli thus standing out prominently. The bodies of the diphtheria bacilli stain a faint purplish-blue; those of other bacilli, including that of Hoffmann, acquire a pale but more definite blue tint, as also do most cocci; some varieties of staphylococci, however, show a uniform reddish-purple coloration. There is no difficulty in deciding whether the purple granules are in bacilli or cocci and specimens may as a rule be examined with considerable rapidity, for the stain appears constant in its action and the film is easily focussed. Only one solution is thus required, and that a stable one, while there are within reason no time limits in its application. These are obvious advantages when dealing with large numbers of cultures.

It may be added that the stain has been found convenient in the examination of swab smears, although polar granules are far from constant in diphtheria bacilli found under these conditions. In order partly to detect Vincent's angina but principally to prevent the introduction of atypical cases of scarlet fever into the diphtheria wards, such examination is made in the receiving room of all cases admitted under certificate of diphtheria. A new slide or coverslip is gently warmed, and the swab, before being used to inoculate the blood-serum tube, is rubbed over its surface, and the toluidine stain applied for about two minutes. Only those cases in which definite diphtheria bacilli showing polar granules have been found in the smear are sent directly to the diphtheria wards; all others are detained in observation rooms until the original diagnosis has been confirmed or gatived by culture. Reference to the register shows that, ong the last 574 cases admitted under certificate of diph-eria, repeated cultures proved negative in 172. Of the naining 402, in which the diagnosis was confirmed by the cteriological examination, 231 had exhibited in the swab near diphtheria bacilli with polar granules, a percentage 57.

LARGE HYDROCELE OF THE TUNICA VAGINALIS.

By C. Lloyd Worrall, L.R.C.P. Lond., L.S.A.,

DISTRICT SURGEON, BARBERTON, TRANSVAAL.

On May 30th I was called to see a native (at the office of he Commissioner of Native Affairs) who was reported to be ' suffering from an extraordinary enlargement of the esticles." Visions of elephantiasis of the scrotum flashed across my mind but these were soon dispelled on examining the case. The history briefly was that the tumour had been gradually developing for four years and that it had never given much pain except that on walking there was a general ache. The patient had no recollection of any injury whatsover to the parts.

I found on examination an enormous scrotal tumour of fairly regular outline, the left side being considerably the larger—it was quite dull all over on percussion and had that elastic feel which strongly suggested fluid. An examination for translucency proved quite negative. There was no impulse on coughing and the spermatic cord could easily be traced to the external rings. The penis was merged into the tumour in such a way that the prepuce alone was in evidence. As I was convinced that the tumour could be no other than an enormous hydrocele I decided to tap it and drew off in all slightly over 78 ounces of fluid. This was contained in two sacs. In the larger one the fluid was dark from what appeared to be disintegrated blood and in the other sac it was the ordinary straw coloured hydrocele fluid.

I venture to report this case as it has one or two points of interest—its enormous size and yet causing little pain or discomfort. Again it was noteworthy that notwithstanding the fact that this hydrocele had been forming for something like four years and reached such a size, the testicles seemed quite normal in size and apparently showed no sign of atrophy. One would have thought that the abnormal pressure of the fluid would have tended to make these organs degenerate and shrink. Another little point worth mentioning is that this native had come in to see the commissioner to report his wife having run away with another native. What a domestic tragedy could possibly have been avoided had this wretched man thought fit in good time to call in the services of a surgeon.

I regret that I am not in reach of any special work on the diseases of the generative organs and therefore am not able to determine the frequency or otherwise of these enormous hydroceles. I note that Erichsen quotes "that Gibbon the historian had an enormous hydrocele, which was tapped by Cline, who drew off six quarts of fluid."

Barberton, Transvaal.

A CASE OF ZONA OF THE FOREARM AND HAND.

By R. E. P. Squibbs, M R C.S. Eng., L.R.C.P. Lond.

The notes of the following case may be of interest on account of the rarity of zona of the forearm and hand. R. Liveing in his "Handbook of Skin Diseases," writes, "On the forearm and hand zona is but rarely seen," and Hilton Fagge says, "In some instances of brachial zoster the vesicles reach down to the finger but this is very exceptional."

On June 15th last I was sent for to see the patient, a stout married woman, aged 61 years, and found her suffering from a typical attack of zona of the left forearm and hand. She complained of severe pain of a neuralgic character. The eruption consisted of several clusters of vesicles on inflamed patches of skin, and were situated on the anterior surface of the forearm, and followed roughly the course of the internal cutaneous nerve. In the palm of the hand a large pemphigus-like bleb had developed and into this some hæmorrhage had evidently taken place. There were also some vesicles on the inner side of the arm, one of which was followed by a small ulcer. The case was successfully treated by the application of hazeline cream and fuller's earth and the internal administration of tonics.

New Lenton.

Medical Societies.

GLASGOW AND EDINBURGH OBSTETRICAL SOCIETIES.

Secondary Operation for Complete Rupture of the Perineum.

The combined summer meeting of these societies was held in Glasgow on June 21st, Dr. J. K. Kelly, President of the Glasgow Obstetrical and Gynæcological Society, being in the chair.

Dr. C. J. Cullingworth, Honorary President of the Glasgow Society, read a paper on the Secondary Operation for Complete Rupture of the Perineum. He said that owing to the new possibilities which have been opened up by advances in abdominal surgery the interest in the older gynæcological operations had of late years somewhat dwindled; and yet some of these, especially the plastic operations, ministered quite as much to the comfort and well-being of the patients as the more showy achievements of modern times. In tracing the history of the operation Dr. Cullingworth mentioned those of Langenbeck in 1853, Jonathan Hutchinson in 1864, Delere' in 1876, and those associated with the names of Emmet, Hegar, Hildebrandt, and Lawson Tait. Emmet's operation, or some modification of it, was the one usually practised in the United States, while in this country the flap-splitting operation of Lawson Tait was perhaps the one most generally adopted. The splitting of the flap by angular scissors instead of laboriously dissecting with a knife simplified and shortened the operation. The weak point was that it left unsutured both the rectal wound and the vaginal wound. In order to be satisfactory any method of operation should fulfil the following conditions: 1. It should restore the perineum as nearly as possible to its original size and shape. The gynæcologist should familiarise himself with the size and shape of the average perineum by taking mental notes of these during his ordinary examination of patients. It was always a temptation to the inexperienced, partly from anxiety lest the new perineum should not be long enough, to carry the new perineum too far forward. This might cause difficulty during labour or dyspareunia. 2. There should be brought into apposition a sufficiently large area of raw surface on the two sides as to make union almost certain. 3. The edges of the rectal side of the tear and those of the vaginal side should be severally brought together by careful suturing. 4. The patient's convalescence should be rendered as free as possible from pain and discomfort. Lawson Tait drew attention to the fact that if the skin was not sutured the patient suffered no pain. Dr. Cullingworth includes only a narrow edge of skin in the sutures and this produces very little pain if there is no tension when they are tied. If no skin is included in the sutures they get buried and the stitches are difficult to get out. 5. The operation should be easy of execution and uncomplicated in its character. 6. The operation should have the result of restoring to the patient efficient control of the bowel. Dr. Cullingworth begins his operation after the method of Lawson Tait by dividing with scissors the cicatricial line of the lower end of the recto-vaginal septum, then upwards on either side and to a less extent backwards, the whole incision roughly representing a capital H. The lateral incisions should be carried forward to the end of the cicatricial tissue, or if that should be indefinite, then to the point where the labia minora commence. The backward cuts are much shorter and facilitate the exposure and union of the divided ends of the sphincter. The vaginal flap should be reflected backwards by scissors or by a knife with the left forefinger as a guard in the rectum. The method of suturing was not a point of importance. Dr. Cullingworth begins by passing a suture entering the skin one-sixth of an inch from the edge of the wound, immediately below the angle of reflection of the vaginal flap. It is passed completely round from one side to the other, quite buried, and going down to the substance of the recto-vaginal septum at the base of the vaginal flap. This braces up the whole perineum and prevents any spaces being left at the bottom of the wound. Stout silkworm gut is used. The rectal tear is now sutured by passing the needle into the tissue close to the rectal mucous membrane and bringing it out half an inch from the edge and then passing over to the other side in a similar manner. The ends are tied and left long in the rectum. Other sutures are inserted in the same manner. Catgut is used for these stitches. The vaginal side of the laceration is then closed by a series of interrupted silkworm-gut sutures; the ends are left long and turn into the vagina. These long ends facilitate very much the removal of the stitches. Then the rest of the perineal sutures are inserted, not passing quite down to the base of the denuded surface. The last one is passed down deep at the side of the anus but no attempt is made to isolate the torn ends of the sphincter and the results are almost invariably satisfactory. Superficial stitches may be required. Two small strips of lint, three inches by three-quarters of an inch, anointed with vaseline, are placed at either side of the stitches. These are kept in place by the ordinary position of the thighs. Vaginal douches are only ordered when there is a purulent or offensive discharge; the wound is washed with wool-sponges. The catheter is usually required for two or three days, or the patient can turn on her hands and knees and pass urine without any more fear of soiling than in the use of the catheter. The patients are kept in bed for 14 days. Enemata are to be avoided, as they may interfere with the union on the rectal aspect. The patient is given a full dose of castor oil 60 hours after the operation and an aperient every other night afterwards. The stitches are removed on the eighth day. It may be reported that a little fæcal matter has escaped; if this matter comes from the perineal wound the opening will probably close but if from the vagina, showing a recto-vaginal fistula, it rarely heals. In again operating on these latter cases it is best to divide all the tissues and to do it all over again.

Dr. D. **Berry Hart** considered Dr. Cullingworth's method was an exceedingly good one. The deep suture into the base of the septum was very important. But he thought a weak point in the method was in having the ends of the stitches of the rectal flap hanging into the rectum. This favoured the contamination of the rectal wound and might have disastrous results on the operation. Dr. Hart favoured the dissecting out of the torn ends of the sphincters in order to secure muscular union after insertion of the sutures. Dr. Kelly (Baltimore) and Dr. Noble (Atlanta) practised a good method to prevent extravasation of fæces into the apex of the rectal flap. After the reflection of the flaps in the usual way they pull down the apex of the rectal gap to the anal orifice instead of burying it, as in Dr. Cullingworth's operation. If the rectal flap is thick it dilates the anus a little but the results are good. Dr. Hart favoured stitching with catgut in tiers.

Dr. W. L. **Reid** had practised many different methods in the last 25 years; now his plan was very much what Dr. Cullingworth had described. Along with repair of the perineum some other operation was frequently performed such as amputation of the cervix. In these cases and whenever there was any discharge that might decompose he used the douche. To prevent any injury to the stitches the douching was carried out by passing a piece of soft rubber tubing into the vagina and irrigating with boric lotion twice daily. He did not employ any dressing but irrigated the wound freely with boric lotion. He had given up using the catheter, but both before and after micturition allowed boric lotion to flow over the wound; there was no fear of harm from fresh urine, only from urine if it were decomposing. He had tried but never once succeeded to lay hold of the ends of the sphincter, but he always passed his stitch deep in the probable position of the ends.

Dr. A. H. **Freeland Barbour** considered it was better to carry the dissection deeper into the recto-vaginal septum than was indicated by Dr. Cullingworth. This permitted the edges of the rectal tear to be brought well together. He never passed any stitch into the bowel, closing the rectal tear by bringing the tissues immediately over the mucous membrane together. He always made an effort to get a good hold of the end of the sphincter.

Dr. **Samuel Sloan** stated that in the discussion Lawson Tait's operation had been lost sight of as it had no rectal stitches. In his experience the perineum was not brought far enough forward. A source of failure was the presence of any purulent discharge and this should be carefully treated as by curetting in a case of purulent endometritis.

Dr. N. T. **Brewis** pointed out that the Americans insisted on the importance of obtaining union of the torn ends of the sphincter. He never found any difficulty in dissecting out the torn ends in his cases. He followed Lawson Tait's method till a few years ago but he then altered it by dissecting out the ends of the sphincter and passing a stitch through one end completely round the rectal gap and then picked up the other end; this stitch was passed through the tissues a little from the rectal mucous membrane. In most cases this plan did very well but in some cases a recto-vaginal fistula resulted due to slipping of the sphincter. To obviate this risk he dissected the rectal flap from above downwards. This flap formed the anterior rectal wall and prevented contamination with fæcal matter, as there was no communication between the wound and the rectum, and prevented the sphincter from slipping down. He considered it an important point to bring the torn ends of the sphincter together and also the fasciæ. He used chromicised catgut all through, passed under the edge of the skin and all buried.

Dr. **Cullingworth**, in reply, stated that he had always got good results without seeking for the ends of the sphincter and that the drawings he had seen of this detail in the operation showed a considerable extension of the area of raw surfaces. He considered this an unnecessary addition to the operation with no distinct gain.

Society for the Study of Disease in Children.—The annual provincial meeting of this society was held on June 17th at the Hospital for Children, Sheffield, Dr. C. H. Willey being in the chair.—Cases and specimens were shown by Dr. Willey, Dr. C. N. Gwynne, Dr. J. H. Wilks, Mr. Simeon Snell, Mr. S. E. Morton, Dr. H. Leader, Dr. Arthur J. Hall, and Dr. J. G. Emanuel.—Dr. Gwynne read a paper on Osteomyelitis and Suppurative Pericarditis in a girl, aged seven years, successfully treated by operation in 1903. The femur and radius were affected. Incisions were made and were followed in three days by parotitis and pericarditis. Ten days later the pericardium was laid open and about ten ounces of pus were evacuated. A tube was inserted and removed on the tenth day. In spite of further pyæmic complications the child recovered. The heart now showed some hypertrophy.—Dr. G. Carpenter and Mr. S. Stephenson reported a case of Tubercle of the Choroid in a girl, aged three years. A very large number of fawn-coloured tubercles, of unusually large size, were found, chiefly in the region of the optic discs. Some of them invaded the retina. A diagnosis of acute miliary tuberculosis was made and verified subsequently. Death resulted 33 days after the onset, 19 after admission to hospital, and five after the diagnosis, which could not have been made with certainty apart from the state of the eyes.—Mr. J. Jackson Clarke read a paper on Certain Practical Points in the Treatment of Congenital Dislocation of the Hip by Lorenz's Method. The shortened muscles must be fully stretched and the great trochanter brought down to, or below, its normal level. In children over four years of age the adductors might require subcutaneous section. He then described the act of reduction, the application of the retention apparatus, the subsequent use of massage and exercises, and the management of special cases.—Mr. R. C. Dun described a case of Median Hare-lip, a very rare deformity. The cleft was exactly in the middle line, the incisor teeth were perfect, and there was no alveolar cleft.—Mr. H. S. Clogg read a paper on Appendicitis in a Hernial Sac, based on two cases in boys, successfully treated by operation. He stated that about 25 per cent. of recorded cases occurred in children; that the condition had been reported in quite young infants; that the appendix in a hernial sac was unduly prone to inflammation; that the condition could not be diagnosed with certainty from strangulation of the appendix or of Meckel's diverticulum; and that most cases were mistaken for strangulated hernia because of the sudden onset, abdominal pain, and the presence of a local irreducible swelling without mpulse on coughing. The presence of fever from the onset, the indefinite character and smaller size of the swelling, and the early occurrence of œdema and redness of the skin were of diagnostic value.—Papers were also read by Dr. Gwynne on Two Cases of Xanthoma Multiplex; by Dr. Wilks on a case of Sudden Death after Needle Puncture for Supposed Empyema, with specimen; by Mr. A. H. Tubby on Osteomyelitis of the Spinal Column; and by Dr. Leader on a case of Hodgkin's Disease.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—The annual meeting of this society was held at the Royal Infirmary on June 20th, Dr. C. F. M. Althorp, the President, being in the chair.—Dr. W. Mitchell read the annual report. —The following officers were elected for next session: President: Mr. W. Handcock. Vice-President. Dr. A. Mantle (Halifax). Honorary treasurer: Dr. H. J. Campbell. Honorary secretaries: Dr. T. J. Wood and Dr. Mitchell. Honorary librarian: Dr. Althorp. Honorary pathologists: Dr. F. W. Eurich, Dr. Phillips, and senior house physician, Royal Infirmary.—Dr. J. Metcalfe then proposed the following motion:—

> That this society do amalgamate with the Bradford division of the British Medical Association and that arrangements as to time and method be either left to a duly appointed subcommittee or decided by this meeting forthwith.

Dr. Metcalfe pointed out the following advantages likely to accrue from amalgamation: (1) that the profession in Bradford would be more united and consolidated than it was at present and would therefore have more influence when called upon to support the honour and interests of the profession; (2) that there would be effected a saving to each member of about 3*s.* per annum; and (3) that there would be fewer meetings necessary were they united than if they existed as separate societies as at present, each society now being under the necessity of holding so many meetings of its own.—Dr. Campbell seconded the motion and pointed out that the Bradford division of the British Medical Association was in danger of degenerating into a merely political and ethical society unless more support were given to the scientific section.—Dr. T. W. Hime opposed the motion and pointed out (1) that the proposed amalgamation would not really be amalgamation but absorption of the society into the British Medical Association; (2) that an amalgamation at present would be virtually signing the death warrant of a society which had achieved 40 odd years of honourable work and traditions, without any certainty that the division could afford them equal privileges and freedom of control; and (3) that all the advantages held out were only hopes and that even the saving of 3*s.* per annum to each member was not a certainty.—There also spoke Dr. R. Mercer, Dr. Johnson, Mr. Vaughan Bateson, Dr. A. Bronner, Dr. Rabagliati, Dr. Wood, Dr. A. H. Bampton, and Dr. Eurich.—The motion was defeated by 44 votes to 23—a majority of nearly 2 to 1.

Reviews and Notices of Books.

Paralysis and other Diseases of the Nervous System in Childhood and Early Life. By JAMES TAYLOR, M.A., M.D. Edin., F.R.C.P. Lond. London: J. and A. Churchill. 1905. Pp. 512. Price 12*s.* 6*d.* net.

Dr. James Taylor has succeeded in presenting within moderate compass an excellent account of diseases of the nervous system as they are met with among children. He describes the various conditions in simple and well-chosen language and the descriptions are illustrated with numerous reproductions of clinical and pathological photographs. Little space is taken up with discussions of disputed points. As is explained in the preface, the work is an expression of the writer's personal observations modified and extended by his knowledge of the views of others. The point of view is mainly clinical. An adequate and clear account of known morbid changes is given wherever the present state of our knowledge admits but long discussions of controverted points in pathology are omitted. The allotment of space to the various diseases has been, on the whole, judiciously adjusted, the more common forms being treated at length so as to permit of full depiction of the numerous variations which the same disease may present in different individuals. Thus meningitis, infantile hemiplegia, cerebral diplegia, hydrocephalus, intracranial tumour, infantile spinal paralysis, epilepsy, and the various forms of muscular dystrophy are exhaustively dealt with. At the same time there is an adequate and interesting account of many rare conditions such as myoclonus, hereditary cerebellar ataxy, myasthenia, family periodic paralysis, and so on. Such common affections as chorea, stammering, and night terrors are also the subjects of attractive chapters. There is such a generally high standard of excellence that there is little to provoke criticism. The chapter on syringomyelia, however, excellent as it is, seems rather dragged in when included in a work on children's diseases, and the same objection applies to the introduction of Huntington's chorea. We think that in a future edition the 20 pages of space devoted to these subjects might be given to other ordinary subjects. The book would gain by a description of migraine in young subjects and a most useful chapter might be given on the nervous symptoms accompanying and following acute febrile diseases, such as measles, pneumonia, enteric fever, and whooping-cough. Further, in a revised edition, there should be uniformity with regard to the use of the adjective denoting the presence of the bacillus tuberculosis, which sometimes appears as "tuberculous" and sometimes as "tubercular." The latter form should not now be used in that sense.

But apart from these friendly suggestions we have nothing but praise for the matter of the work and for the way in which it is presented. The style throughout is clear and very readable, remarkably so considering the complexity of the subject. The descriptions are liberally illustrated by well selected clinical cases and the numerous clinical and pathological photographs are well chosen and beautifully reproduced. Altogether we can congratulate Dr. Taylor on the production of a well-written book which will be useful alike to the busy practitioner and to the neurologist.

Principles of Physiological Psychology. By WILHELM WUNDT. Translated from the Fifth German Edition (1902) by E. B. TITCHENER, Sage Professor of Psychology in the Cornell University. Vol. I. With 105 figures in the text. London: Swan Sonnenschein and Co., Limited. 1904. Pp. 347. Price 12*s.*

THE present volume covers the first 338 pages of the well-known work of the professor of philosophy in the University of Leipsic, being the Introduction and Part I., On the Bodily Substrate of the Mental Life. The complete work consists of six parts. Some 28 years have elapsed between the publication of the first and fifth editions of the work. The author considers that when first he published his book Fechner's "Elemente der Psychophysik" constituted the only successful attempt to apply exact procedure to psychological problems. To-day accuracy of method is freely applied in this domain and workers therein are no longer challenged to prove that their endeavours are legitimate. There is a lengthy introduction to the work, comprising a philosophical survey of the subject of physiological psychology, which science is shown to involve the application of experiment and a knowledge of the bodily substrata of the mind. The reform which it seeks to accomplish in psychological investigation is compared with the revolution brought about in the natural sciences by the introduction of the experimenta method. It is necessary to remember that physiological psychology is primarily *psychology*. The six chapters of this volume deal with the Organic Evolution of Mental Function, the Structural Elements of the Nervous System, the Physiological Mechanics of Nerve Substance, the Morphological Development of the Central

Organs, the Course of the Paths of Nervous Conduction, and the Physiological Functions of the Central Parts. The criteria of mind and the range of the mental life find consideration under the first of these headings. Consciousness, in the sense of "continuity of internal states," is, it is maintained, a universal possession of living organisms from man to the protozoa. The manifestations of life, even among the lowest protozoa, are only explicable on the hypothesis that they possess a mind. The author regards it as a highly probable hypothesis that the beginnings of mental life may be dated back to the beginnings of life. The development of the nervous system is sketched at this stage and its morphological elements are described. The usefulness of the neuron theory as a working hypothesis is recognised, whilst due mention is made of the opposition which it finds, though it does not seem to us that the reasons for that opposition, so far as they depend upon the work of Apáthy and Bethe upon intracellular structure, are adequately set forth.

The functions attributed to the various constituents of the nerve cell and to its processes are discussed. Referring to the amœboid movements of the dendrites, the author very properly dismisses as imaginary the psycho-physical explanations of sleep and waking, dissociation of consciousness, and the like, that certain authors, chiefly Italian, have erected upon them. A consideration of the general principles and problems of a "Mechanics of Innervation" and of the course of the processes of stimulation in the nerve-fibre leads up to the development of a theory of nervous excitation. This is based upon a supposed molecular state of nervous substance in which positive and negative molecular work are in performance simultaneously. The action of stimulus-shock upon this state is elaborately discussed. As between nerve cell and nerve fibre the difference is pointed out, that the characteristic of the latter is to form products of combustion associated with positive work, whereas the cell is concerned with the production of highly complex bodies in which potential work is stored. The chief consumer of this store will be the peripheral nerves and their organs. There follows here a description of the physiological relationship obtaining between the central substance and the nerve fibres.

Chapters IV., V., and VI. deal almost entirely with the morphological development, anatomy, and physiology of the nervous system. The subject-matter of these parts, covering 240 pages, is in the main familiar to the student of the nervous system. The anatomical description closes with an account of the structure of the cerebral cortex. It is shown that whilst the essential morphological elements and their general arrangement are the same for all parts there are different degrees of development of certain layers and elements according to the special function of the various parts. In particular the probable symptomatic importance of two kinds of cell is pointed out: the pyramidal cells, with their longitudinally-directed fibres, and the stellate cells with their fibrillar reticula, the former characteristic of the centro-motor region and serving as points of departure of the great centrifugal nerve-paths, the latter of the sensory regions, and probably serving mainly as terminal stations of centripetal conduction. Then in all regions of the cortex the outermost layer with its reticular formation seems to form a meeting place for conduction-paths of the most varied kinds. In reference to the much-disputed question whether the different cortical regions possess a specifically different structure which may serve as a basis for discrimination of faculties, the researches of Ramon y Cajal and others are regarded as leading to the conclusion that the different modes of cerebral activity are founded not upon the specific character of the structural elements but solely upon their different modes of connexion. The general principles of the processes of central conduction are sketched, such as the principle of manifold representation of peripheral regions at the centre and that of the ascending complication of conduction paths. The functions of the nervous system are sufficiently dealt with, as deduced from operative procedure, comparative anatomy, and anthropology. The hypotheses of localisation, the "sense-centre" theory of Meynert, and the modern association theory are admirably discussed. The last few pages give illustrations of the psycho-physical analysis of certain cerebral functions; as was to be expected, the author's theory of apperception and an apperception-centre is set forth and upheld against the opposition it has encountered.

The difficulty of translation of such a work as the above, already great from the nature of the subject, must have been considerably enhanced by Professor Wundt's style, often described as diffuse and obscure. Professor Titchener is greatly to be congratulated on his task. It is to be hoped that the remaining parts of the last edition of this great work may be translated ere long.

Physiological Economy in Nutrition, with special reference to the Minimal Proteid Requirement for the Healthy Man. By RUSSELL H. CHITTENDEN, Professor of Physiological Chemistry in Yale University. With 16 photographic reproductions of athletes and groups of soldiers. London: William Heinemann. 1905. Pp. 478. Price 14s.

THE name of Professor Chittenden is itself a guarantee of the accuracy of this experimental research which goes far to modify profoundly the usually accepted standards as to the minimum amount of proteid required in a so-called standard diet. No subject can be primarily of greater physiological importance for the welfare of the human race than the subject of nutrition. How is the highest condition of health and strength to be established? Even physiologists vary greatly in their estimates as to the true physiological necessities of the body for proteid foods. The standard of diet generally accepted for an adult man of average body weight (from 70 to 75 kilogrammes) doing a moderate amount of work is that of Professor Carl Voit of Munich: proteids, 118 grammes, of which 105 should be absorbable; carbohydrates, 500 grammes; and fats, 56 grammes, with a total fuel value of 3000 large calories, to keep the body in equilibrium.

Average Diets.

	grms.	grms	grms.	grms.	grms.	grms.	grms
Proteid ...	130	100	131	134	125	114	105
Carbohydrates ...	550	240	494	523	400	551	541
Fats ...	40	100	68	79	125	54	63
Fuel value (calories)	3160	2324	3195	3436	3315	3229	3235

These figures show the dietetic standard and the dietetic habits adopted by mankind but there is no evidence that they represent the real needs or requirements of the body. There is experimental evidence to show the possibility of much lower standards of diet sufficing to meet the real physiological needs of the body. Thus Kumagawa, studying the diet of the Japanese, experimenting on himself (27 years old and weighing 48 kilogrammes), found with a purely vegetable diet containing per day 54·7 grammes of proteid, equal to 8·75 grammes of nitrogen, 2·5 grammes of fat and 569·8 grammes of carbohydrate, that the average daily excretion of nitrogen by the urine was 6·07 grammes and in the fæces 2·03 grammes—i.e., of the 54·7 grammes of nitrogen-containing food (chiefly rice) only 37·8 were absorbed and 12·7 passed out with the fæces. The total fuel value of the food absorbed per day was 2478 large calories. It is self-evident that the smallest amount of food that will serve to keep the body in a state of high efficiency is physiologically not only the most economical, but as the products of proteid metabolism are a constant menace to the well-being of the body both Scylla and Charybdis are avoided by reducing the amount of proteid to the limits of safety.

The singularly elaborate and fully detailed experiments carried out during many months on professional men, on soldiers of the Hospital Corps of the United States Army, on trained athletes of the American universities, make it plain that our accepted dietary standards are altogether too high and conclusively prove that the physiological needs of the body can be met by a greatly reduced proteid intake, with establishment of continued nitrogenous equilibrium, and with actual gain to the body. This, moreover, can be accomplished without increase in the daily intake of non-nitrogenous foods.

The careful analyses of the daily dietary, of the various excreta, all scheduled in a tabular form and occupying many pages of elaborate data justify, we think, completely the general conclusion regarding the professional class "that a healthy man whose occupation is such as not to involve excessive muscular work but whose activity is mainly mental rather than physical, can live on a much smaller amount of proteid food than is usually considered essential for life without loss of mental or physical strength and vigour and with the maintenance of body and nitrogen equilibrium." The ordinary professional man need not clog his system and inhibit his power of work by the ingestion of any such quantities of proteid food as the ordinary dietetic standards call for and "he may practise an economy in the use of proteid food equal to a saving of one-half to two-thirds the amount called for by existing dietary standards and without increasing the non-nitrogenous food consumed."

The results obtained with a body of United States soldiers living on a prescribed diet and exposed to the stress and strain of military discipline confirmed the results arrived at in the case of professional workers. A metabolism of less than 50 grammes of proteid per day was quite sufficient for the needs of the body and a fuel value of from 2500 to 2600 calories was ample to meet the requirements of these men. Why, therefore, metabolise 105 grammes of proteid per day! This condition of lowered proteid metabolism was maintained for five months in 13 soldiers on amounts of proteid food not more than one-half called for by ordinary standard dietaries and this without increase of non-nitrogenous food. While their body weight, nitrogen equilibrium, physical strength and vigour, reaction time, and general composition of blood "all remained unimpaired under a daily diet involving the metabolism of only seven to eight grams of nitrogen per day and with a fuel value of less than 2800 calories per day." Indeed, such economy led to improved working of the neuro-muscular machinery, while all the subjects of the experiment were less conscious of fatigue than formerly. No facts are in evidence to show whether the power of resistance to disease is diminished in any way by a low proteid intake.

Undoubtedly, some of the products of proteid katabolism are more or less dangerous to the well-being of the organism; hence there seems additional justification for the belief that "safety" lies in adopting dietetic habits that are in accord with the real needs of the body.

The author makes a powerful appeal—or rather reiterated appeals, for the same statements recur—for what may be called a simple mode of living—if the phrase "simple life" has become too hackneyed. Physiological economy is not restriction to a vegetable diet, it is not even prohibition, but temperance. "Moderation in diet, especially in the taking of proteid foods, means a great saving in the wear and tear of the bodily machinery." The whole story may be summed up in the statement that in general man eats far too much proteid or albuminous food.

This is a work—a careful experimental research—that must attract the attention and the careful consideration not only of the physician and the physiologist, but it also claims the attention of the economist and the sociologist. To all of these we commend its careful perusal and we feel convinced that few who read the elaborate record of this careful chemical and exhaustive research will fail to agree with its fundamental proposition—viz., the question of intemperance in the daily dietary, more especially as regards the consumption of proteids.

Radiotherapy and Phototherapy, including Radium and High Frequency Currents. By CHARLES WARRENNE ALLEN, M.D., Professor of Dermatology in the New York Post-graduate Medical School, &c. London: Henry Kimpton. 1905. Pp. 618. Price 22*s.* 6*d.* net.

THE author's aim has been to produce a handy volume dealing with all the subjects referred to in its title for the use of students and practitioners. It may be fairly conceded that he has been successful. The work is divided into seven parts, the first of which relates to general considerations upon radiology, apparatus, and technique. All necessary information and instruction are here given, with a notable absence of redundant material.

Part II. deals with the use of the x rays in medical and surgical diagnosis—a separate chapter being devoted to each. Part III., the longest and most important section, treats of the therapeutic applications of the x rays. Under "General Considerations" the author is very insistent on "the necessity of having trained and intelligent medical men in charge of all treatments. No electrician, however skilled in physics or even a knowledge of radiotherapy, should be considered a competent therapeutist. It requires good medical and clinical training, and tact besides, to enable one to safely and successfully conduct x ray therapeutic applications, and, while it is all the better if the radiotherapist is at the same time a practical electrician, it is absolutely necessary that he be a finished clinician." We commend the above to the consideration of those who think that anyone knowing how to manipulate a few switches can practise radiotherapy with success.

In the treatment of cancer the author indicates a desirable coöperation between the radiotherapist and the surgeon. In inoperable cases he advises the removal of as much as possible of the cancerous mass by the surgeon, relying on the x rays to attack and to destroy what remains. Separate chapters are devoted to cancer, epithelioma and rodent ulcer, sarcoma, and skin diseases—the last forming, as might be expected, one of the best chapters in the book. The author is essentially a dermatologist and he has well maintained his reputation here. Details of many cases are given and the illustrations are exceptionally clear and well produced. The x ray burn and other deleterious effects of the x rays are fully described and the histological changes and action on bacteria are dealt with in separate chapters.

Part IV., on Light, opens with a chapter entitled "Therapeutic Indications for the Employment of Light," and is remarkable on account of the entire absence of anything bearing on its title, dealing as it does almost entirely with the historical aspect of the subject. The physical properties of light next receive attention and later the action of light on bacteria is treated in a full yet concise manner. The section closes with a chapter on general phototherapeutics. This part is really an introduction to the next one entitled "Actinotherapy," in which the various methods and the diseases to which they are applicable are all treated in greater detail.

Part VI. is made up of a single chapter on radio-activity.

Organs, the Course of the Paths of Nervous Conduction, and the Physiological Functions of the Central Parts. The criteria of mind and the range of the mental life find consideration under the first of these headings. Consciousness, in the sense of "continuity of internal states," is, it is maintained, a universal possession of living organisms from man to the protozoa. The manifestations of life, even among the lowest protozoa, are only explicable on the hypothesis that they possess a mind. The author regards it as a highly probable hypothesis that the beginnings of mental life may be dated back to the beginnings of life. The development of the nervous system is sketched at this stage and its morphological elements are described. The usefulness of the neuron theory as a working hypothesis is recognised, whilst due mention is made of the opposition which it finds, though it does not seem to us that the reasons for that opposition, so far as they depend upon the work of Apáthy and Bethe upon intracellular structure, are adequately set forth.

The functions attributed to the various constituents of the nerve cell and to its processes are discussed. Referring to the amœboid movements of the dendrites, the author very properly dismisses as imaginary the psycho-physical explanations of sleep and waking, dissociation of consciousness, and the like, that certain authors, chiefly Italian, have erected upon them. A consideration of the general principles and problems of a "Mechanics of Innervation" and of the course of the processes of stimulation in the nerve-fibre leads up to the development of a theory of nervous excitation. This is based upon a supposed molecular state of nervous substance in which positive and negative molecular work are in performance simultaneously. The action of stimulus-shock upon this state is elaborately discussed. As between nerve cell and nerve fibre the difference is pointed out, that the characteristic of the latter is to form products of combustion associated with positive work, whereas the cell is concerned with the production of highly complex bodies in which potential work is stored. The chief consumer of this store will be the peripheral nerves and their organs. There follows here a description of the physiological relationship obtaining between the central substance and the nerve fibres.

Chapters IV., V., and VI. deal almost entirely with the morphological development, anatomy, and physiology of the nervous system. The subject-matter of these parts, covering 240 pages, is in the main familiar to the student of the nervous system. The anatomical description closes with an account of the structure of the cerebral cortex. It is shown that whilst the essential morphological elements and their general arrangement are the same for all parts there are different degrees of development of certain layers and elements according to the special function of the various parts. In particular the probable symptomatic importance of two kinds of cell is pointed out: the pyramidal cells, with their longitudinally-directed fibres, and the stellate cells with their fibrillar reticula, the former characteristic of the centro-motor region and serving as points of departure of the great centrifugal nerve-paths, the latter of the sensory regions, and probably serving mainly as terminal stations of centripetal conduction. Then in all regions of the cortex the outermost layer with its reticular formation seems to form a meeting place for conduction-paths of the most varied kinds. In reference to the much-disputed question whether the different cortical regions possess a specifically different structure which may serve as a basis for discrimination of faculties, the researches of Ramon y Cajal and others are regarded as leading to the conclusion that the different modes of cerebral activity are founded not upon the specific character of the structural elements but solely upon their different modes of connexion. The general principles of the processes of central conduction are sketched, such as the principle of manifold representation of peripheral regions at the centre and that of the ascending complication of conduction paths. The functions of the nervous system are sufficiently dealt with, as deduced from operative procedure, comparative anatomy, and anthropology. The hypotheses of localisation, the "sense-centre" theory of Meynert, and the modern association theory are admirably discussed. The last few pages give illustrations of the psycho-physical analysis of certain cerebral functions; as was to be expected, the author's theory of apperception and an apperception-centre is set forth and upheld against the opposition it has encountered.

The difficulty of translation of such a work as the above, already great from the nature of the subject, must have been considerably enhanced by Professor Wundt's style, often described as diffuse and obscure. Professor Titchener is greatly to be congratulated on his task. It is to be hoped that the remaining parts of the last edition of this great work may be translated ere long.

Physiological Economy in Nutrition, with special reference to the Minimal Proteid Requirement for the Healthy Man. By RUSSELL H. CHITTENDEN, Professor of Physiological Chemistry in Yale University. With 16 photographic reproductions of athletes and groups of soldiers. London: William Heinemann. 1905. Pp. 478. Price 14*s.*

THE name of Professor Chittenden is itself a guarantee of the accuracy of this experimental research which goes far to modify profoundly the usually accepted standards as to the minimum amount of proteid required in a so-called standard diet. No subject can be primarily of greater physiological importance for the welfare of the human race than the subject of nutrition. How is the highest condition of health and strength to be established? Even physiologists vary greatly in their estimates as to the true physiological necessities of the body for proteid foods. The standard of diet generally accepted for an adult man of average body weight (from 70 to 75 kilogrammes) doing a moderate amount of work is that of Professor Carl Voit of Munich: proteids, 118 grammes, of which 105 should be absorbable; carbohydrates, 500 grammes; and fats, 56 grammes, with a total fuel value of 3000 large calories, to keep the body in equilibrium.

Average Diets.

Fats ...	40	100	68	79	125	54	63
Fuel value (calories)	3160	2324	3195	3436	3315	3229	3235

These figures show the dietetic standard and the dietetic habits adopted by mankind but there is no evidence that they represent the real needs or requirements of the body. There is experimental evidence to show the possibility of much lower standards of diet sufficing to meet the real physiological needs of the body. Thus Kumagawa, studying the diet of the Japanese, experimenting on himself (27 years old and weighing 48 kilogrammes), found with a purely vegetable diet containing per day 54·7 grammes of proteid, equal to 8·75 grammes of nitrogen, 2·5 grammes of fat and 569·8 grammes of carbohydrate, that the average daily excretion of nitrogen by the urine was 6·07 grammes and in the fæces 2·03 grammes—i.e., of the 54·7 grammes of nitrogen-containing food (chiefly rice) only 37·8 were absorbed and 12·7 passed out with the fæces. The total fuel value of the food absorbed per day was 2478 large calories. It is self-evident that the smallest amount of food that will serve to keep the body in a state of high efficiency is physiologically not only the most economical, but as the products of proteid metabolism are a constant menace to the well-being of the body both Scylla and Charybdis are avoided by reducing the amount of proteid to the limits of safety.

The singularly elaborate and fully detailed experiments carried out during many months on professional men, on soldiers of the Hospital Corps of the United States Army, on trained athletes of the American universities, make it plain that our accepted dietary standards are altogether too high and conclusively prove that the physiological needs of the body can be met by a greatly reduced proteid intake, with establishment of continued nitrogenous equilibrium, and with actual gain to the body. This, moreover, can be accomplished without increase in the daily intake of non-nitrogenous foods.

The careful analyses of the daily dietary, of the various excreta, all scheduled in a tabular form and occupying many pages of elaborate data justify, we think, completely the general conclusion regarding the professional class "that a healthy man whose occupation is such as not to involve excessive muscular work but whose activity is mainly mental rather than physical, can live on a much smaller amount of proteid food than is usually considered essential for life without loss of mental or physical strength and vigour and with the maintenance of body and nitrogen equilibrium." The ordinary professional man need not clog his system and inhibit his power of work by the ingestion of any such quantities of proteid food as the ordinary dietetic standards call for and "he may practise an economy in the use of proteid food equal to a saving of one-half to two-thirds the amount called for by existing dietary standards and without increasing the non-nitrogenous food consumed."

The results obtained with a body of United States soldiers living on a prescribed diet and exposed to the stress and strain of military discipline confirmed the results arrived at in the case of professional workers. A metabolism of less than 50 grammes of proteid per day was quite sufficient for the needs of the body and a fuel value of from 2500 to 2600 calories was ample to meet the requirements of these men. Why, therefore, metabolise 105 grammes of proteid per day? This condition of lowered proteid metabolism was maintained for five months in 13 soldiers on amounts of proteid food not more than one-half called for by ordinary standard dietaries and this without increase of non-nitrogenous food. While their body weight, nitrogen equilibrium, physical strength and vigour, reaction time, and general composition of blood "all remained unimpaired under a daily diet involving the metabolism of only seven to eight grams of nitrogen per day and with a fuel value of less than 2800 calories per day." Indeed, such economy led to improved working of the neuromuscular machinery, while all the subjects of the experiment were less conscious of fatigue than formerly. No facts are in evidence to show whether the power of resistance to disease is diminished in any way by a low proteid intake.

Undoubtedly, some of the products of proteid katabolism are more or less dangerous to the well-being of the organism; hence there seems additional justification for the belief that "safety" lies in adopting dietetic habits that are in accord with the real needs of the body.

The author makes a powerful appeal—or rather reiterated appeals, for the same statements recur—for what may be called a simple mode of living—if the phrase "simple life" has become too hackneyed. Physiological economy is not restriction to a vegetable diet, it is not even prohibition, but temperance. "Moderation in diet, especially in the taking of proteid foods, means a great saving in the wear and tear of the bodily machinery." The whole story may be summed up in the statement that in general man eats far too much proteid or albuminous food.

This is a work—a careful experimental research—that must attract the attention and the careful consideration not only of the physician and the physiologist, but it also claims the attention of the economist and the sociologist. To all of these we commend its careful perusal and we feel convinced that few who read the elaborate record of this careful chemical and exhaustive research will fail to agree with its fundamental proposition—viz., the question of intemperance in the daily dietary, more especially as regards the consumption of proteids.

Radiotherapy and Phototherapy, including Radium and High Frequency Currents. By CHARLES WARRENNE ALLEN, M.D., Professor of Dermatology in the New York Post-graduate Medical School, &c. London: Henry Kimpton. 1905. Pp. 618. Price 22*s.* 6*d.* net.

THE author's aim has been to produce a handy volume dealing with all the subjects referred to in its title for the use of students and practitioners. It may be fairly conceded that he has been successful. The work is divided into seven parts, the first of which relates to general considerations upon radiology, apparatus, and technique. All necessary information and instruction are here given, with a notable absence of redundant material.

Part II. deals with the use of the x rays in medical and surgical diagnosis—a separate chapter being devoted to each. Part III., the longest and most important section, treats of the therapeutic applications of the x rays. Under "General Considerations" the author is very insistent on "the necessity of having trained and intelligent medical men in charge of all treatments. No electrician, however skilled in physics or even a knowledge of radiotherapy, should be considered a competent therapeutist. It requires good medical and clinical training, and tact besides, to enable one to safely and successfully conduct x ray therapeutic applications, and, while it is all the better if the radiotherapist is at the same time a practical electrician, it is absolutely necessary that he be a finished clinician." We commend the above to the consideration of those who think that anyone knowing how to manipulate a few switches can practise radiotherapy with success.

In the treatment of cancer the author indicates a desirable coöperation between the radiotherapist and the surgeon. In inoperable cases he advises the removal of as much as possible of the cancerous mass by the surgeon, relying on the x rays to attack and to destroy what remains. Separate chapters are devoted to cancer, epithelioma and rodent ulcer, sarcoma, and skin diseases—the last forming, as might be expected, one of the best chapters in the book. The author is essentially a dermatologist and he has well maintained his reputation here. Details of many cases are given and the illustrations are exceptionally clear and well produced. The x ray burn and other deleterious effects of the x rays are fully described and the histological changes and action on bacteria are dealt with in separate chapters.

Part IV., on Light, opens with a chapter entitled "Therapeutic Indications for the Employment of Light," and is remarkable on account of the entire absence of anything bearing on its title, dealing as it does almost entirely with the historical aspect of the subject. The physical properties of light next receive attention and later the action of light on bacteria is treated in a full yet concise manner. The section closes with a chapter on general phototherapeutics. This part is really an introduction to the next one entitled "Actinotherapy," in which the various methods and the diseases to which they are applicable are all treated in greater detail.

Part VI. is made up of a single chapter on radio-activity.

It forms an excellent epitome of all the literature up to date bearing on radio-active substances and their application to the treatment of disease.

The final section is devoted to high frequency currents. It takes up the concluding 50 pages of the volume and contains all that is really known of the subject up to the present time. In summing up the author considers that in high frequency currents we have a therapeutic agent that will be more appreciated as time goes on. He considers, and many will agree, that in local applications this form of electricity has shown its greatest field of usefulness.

The book is well got up and well illustrated. It is sure to prove a very handy and valuable volume to those who are interested in these branches of physical therapeutics.

LIBRARY TABLE.

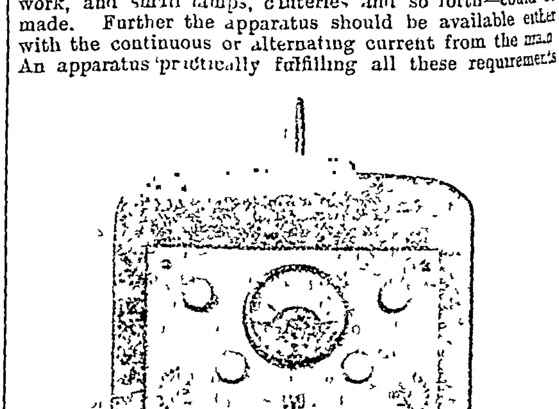
Précis d'Accouchement Par Dr. LOUIS DUBRISAY, Ancien Chef de Clinique à la Faculté de Paris, et Dr. CYRILLE JEANNIN, Chef de Clinique adjoint à la Faculté de Paris. With 113 figures. Paris. F. R. de Rudeval. Pp. 736. Price 9 francs.—In preparing this work the authors have endeavoured to make it essentially clinical and practical in character. They have treated in especial detail the various methods of treatment and the different operative procedures recommended. Questions of less importance are discussed more briefly, but they are all duly considered and the work is a complete treatise on the art of obstetric medicine. It is divided into two parts the first is concerned with the physiology of pregnancy, labour, and the puerperium, whilst the second deals with the pathology of these three conditions. The book is written in a clear and simple manner and the authors make frequent use of short paragraphs and tables. In many instances it is especially full, as for example in the section dealing with the care of premature infants, and it will no doubt prove of value to the students for whom it is written.

The Nutrition of the Infant. By RALPH VINCENT, M.D. Durh. Second edition, revised and enlarged. London: Baillière, Tyndall, and Cox. 1904. Pp. 321. Price 10*s.* 6*d.*—A review of the first edition of this work appeared in THE LANCET of March 19th, 1904, p. 808. In its present form we notice few alterations of importance although the author with an extended experience of the laboratory method of preparing milk mixtures is more strongly convinced than ever that this method is the best. As the result of employing so scientific and exact a method as that which Dr. Vincent relies upon in his practice and describes in his book this conclusion is exactly what was to be expected. By employing accurate formulæ and measuring the amounts of the various ingredients employed in the preparation of the milk mixtures it is possible to keep a systematic record of the dietary and of the results achieved. This is, we take it, the only rational means of gaining a progressive knowledge of the feeding of infants. It is not so important to have a perfect food as to have a useful experience of the best methods of employing the material with which we have to work. Those who employ haphazard methods and despise the so-called percentage method of feeding or, in other words, the use of weights and measures, are very unlikely to obtain uniformly good results, or even to advance in the clinical knowledge which is necessary for the satisfactory feeding of infants. They may, indeed, occasionally obtain brilliant results but there will be no uniformity in their achievements. Nevertheless we cannot help thinking that Dr. Vincent is too restricted in his dietetic resources and, further, that he is too severe on certain of the expedients employed by clinicians of great experience in the feeding of infants. For instance, he describes all sugars other than milk sugar as foreign bodies and he denies to carbohydrates a position among the foods, and, further, he seems to think that the boiling or sterilisation of milk deprives it of most of its virtues and that its use necessarily leads to rickets, scorbutus, or some other manifestations of malnutrition. As with laboratory milk so with sterilised milk, success or failure depends more on the manner in which it is employed than on the character of the milk *per se.* We imagine that few authorities would claim that sterilised milk was better adapted for the purpose of infant feeding than pure, fresh milk, but probably most people would consider that it has advantages over milk which is seriously contaminated by micro organisms. In most respects, however, we consider that the views which Dr. Vincent has expressed in this volume are thoroughly sound; at any rate, he advocates a method which is capable of great refinement and nice adjustment, and one which is calculated to give progressively better results as the man who uses it progresses in clinical experience and in a knowledge of the practical applications of variously modified milks.

New Inventions.

IMPROVED HIGH POTENTIAL APPARATUS IN ELECTRO-THERAPEUTIC APPLICATIONS.

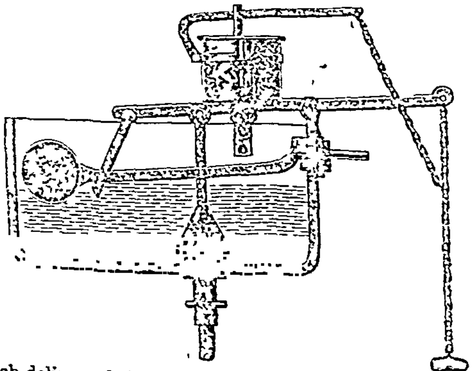
DAY by day further additions are made to the electro-therapeutic armamentarium and as the applications increase it is desirable that whilst the equipment should be comprehensive it should also be made as convenient and compact as possible. It would be a great gain, for example, if with one apparatus all the applications of the electric current—e.g., x ray work, high frequency currents, sinusoidal currents, vibratory massage and other mechanical work, and small lamps, cauteries and so forth—could be made. Further the apparatus should be available either with the continuous or alternating current from the main. An apparatus practically fulfilling all these requirements and occupying but a relatively small space was shown by Messrs. Isenthal and Co., of 85, Mortimer-street, London, W., at the recent conversazione of the Royal Society where it naturally attracted the interest of the medical visitors. The upper part of the apparatus, which is known as the Grisson resonance apparatus, is shown in the accompanying illustration. The reverser situated at the base of the



stats and switches and protected by a guard rail is in the form of a modified commutator with two slip rings upon which four brushes bear, those for ommutator being adjustable laterally and angularly. It iven by means of a quarter horse power semi-inclosed rio motor, a flexible coupling being interposed, and the d is regulated by a rheostat. The free end is fitted to flexible shafts for surgical instruments, vibrators, &c. reverser dispenses with the interrupter of the old ction coil and has the very distinct advantages that it ks without sparking, contains no mercury to "sicken," no expensive platinum contacts to burn. The conser may be charged from one to 200 times per second, ng with the resonance coils anything up to 1000 sparks second between the terminals of the coil. The consers are situated in a cupboard (not shown in the ure) beneath the upper part of the apparatus and sist of two or more steel vessels fitted with a terminal. lid carries two folded aluminium plates kept in position glass insulated uprights fixed to a false bottom in the cell such a way as to make short circuits an impossibility. dielectric is only a minute fraction of a millimetre in kness, being represented by a film of aluminium hydroxide ned electrolytically on the surface of the aluminium tes. The electrolyte is a special alkaline solution. The acity is enormously increased by adopting such an exmely thin separating dielectric. It exceeds for each conser 100 microfarads at a charging potential of 110 volts d 50 periods and will discharge on a 100-volt circuit at a e up to 15 ampères through the coil. The resonance coil s no condenser and gives sparks up to 16 inches in length d of immense magnitude. The coil is said to be equal in iciency to an ordinary coil of 28 inch spark-length worked th an interrupter. The reserve of energy in the Grisson sonator amounts, it is stated, to more than 100 per cent. e resonance coil acts by suddenly forcing current through e primary coil in a succession of impulses. The equipent includes a very ingenious arrangement of controlling ar with coarse and fine adjustment rheostats for the imary or alternating circuit, control lamps for the consers and magnet, hot wire ammeter for primary circuit, ange-over switches, fuses, and double pole switches. The ntrolling gear may be mounted on a wall, switchboard, or tached to a cabinet as shown in the illustration. This binet is designed for x ray work, high frequency, electroagnetic therapy, vibration, cautery, sinusoidal currents, c. One important feature of the apparatus is the simple anner in which its working may be controlled and the perating of the switches for the various applications is free rom complication while the chances of "turning on the rong tap" are reduced to an impossibility by the special isposition of the connexions. There is a rheostat for the otor and until this is in operation no effects, of course, are btainable.

AUTOMATIC DISINFECTANT DELIVERY MACHINE.

FROM time to time a number of appliances have been levised providing for the automatic discharge of a disinfectant into the water used for flushing the water closet and those succeed best which are simple in construction and which deliver a definite quantity of disinfectant each time the flushing cistern is emptied. The merit of simplicity as well as efficiency certainly belongs to the apparatus of the Automatic Disinfectant Delivery Machine Company, Limited, of 2 and 4, Tudor-street, London, E.C. The manner of working of the apparatus will readily appear from the accompanying illustration. A small metal container is fastened by means of a thumbscrew to the top of the cistern. A valve in this container is operated by a chain attached to the chain of the cistern itself. When the cistern chain is pulled the valve of the disinfectant container is opened and a measured volume of the fluid is released which, mixing with the flush, provides an effective disinfecting "wash down." It is a decided advantage also that the method leaves in the trap and pan a quantity of disinfecting fluid so that any return gases that may escape would be submitted to the action of the disinfecting agent. The fluid used in the model with which we made a practical trial appeared to consist of an alkaline mixture of phenols and pine oil but obviously any other fluid may be used for the purpose. The disinfectant container, of course, requires to be filled at intervals, but for ordinary purposes it holds sufficient disinfectant for a month's use. Assuming that the addition of a disinfectant fluid to excreta is desirable, this plan seems to be a very convenient and satisfactory way of effecting that end.



MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER XIX.[1]

THE AMENDMENT OF THE MEDICAL ACTS.

The Constitution of the General Medical Council.—The One-Portal System.—The Legal Prohibition of Quackery.

MEDICAL organisation, however perfect, and public opinion, however sympathetic, will not accomplish the removals of all the evils that have been displayed. They would do a great deal and would pave the way for more but the law of the land expressly permits a state of things which cannot be altered by any united effort on the part of medical men, be it ever so kindly received by the people. As long as there are over 20 ways of entering the medical profession so long will there be a certain amount of disorder in medical education and jealousy in the ranks of medical practitioners; and as long as the only existing legislation against quackery is limited to the imposition of a small fine for falsely pretending to be a medical man, so long will the charlatan, run riot amongst us. As both the disorderly condition of medical education and the impunity of quackery depend upon the wording of the Medical Acts it is not surprising that all medical reformers have put in the front of their programme the amendment of these Acts. The suggested amendments are usually as follows: (1) the alteration of the *personnel* of the General Medical Council so as to make it a more representative body; (2) the institution of one State examination by which the medical profession must be entered; and (3) the legal prohibition of medical practice by persons not registered as medical men. We may consider the amendments in that order.

1. *The Alteration of the Personnel of the General Medical Council.*

The General Medical Council, as the Council is at present constituted, is not representative of the medical profession. It has been generally assumed that, if its constitution were altered until the Council was more representative in character, its deliberations would be of a more practical sort, while, its intimacy with the troubles of the general practitioner being greater, it would be more capable of bringing public needs into line with medical service and of interpreting professional views so that laymen would recognise their justice. These things and more have been assumed on apparently good grounds, but it must be remembered that until a reconstituted Council has actually taken over the work to be done assumption is all that we have to go upon.

---

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII. XIII., XIV., XV., XVI., XVII. and XVIII. were published in THE LANCET of Feb. 18th (p. 447) and 25th (p. 517), March 4th (p. 593), 18th (p. 736), and 25th (p. 817), April 1st (p. 877), 15th (p. 1017), 22nd (p. 1089), and 29th (p. 1151), May 6th (p. 1218), 13th (p. 1287), 20th (p. 1375), and 27th (p. 1449), June 3rd (p. 1533), 10th (p. 1584), 17th (p. 1651), and 24th (p. 1741), and July 1st (p. 43), 1905, respectively.

It forms an excellent epitome of all the literature up to date bearing on radio-active substances and their application to the treatment of disease.

The final section is devoted to high frequency currents. It takes up the concluding 50 pages of the volume and contains all that is really known of the subject up to the present time. In summing up the author considers that in high frequency currents we have a therapeutic agent that will be more appreciated as time goes on. He considers, and many will agree, that in local applications this form of electricity has shown its greatest field of usefulness.

The book is well got up and well illustrated. It is sure to prove a very handy and valuable volume to those who are interested in these branches of physical therapeutics.

LIBRARY TABLE.

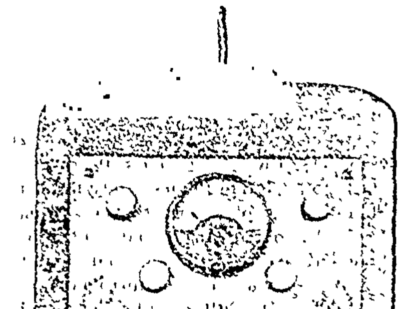
Précis d'Accouchement. Par Dr. LOUIS DUBRISAY, Ancien Chef de Clinique à la Faculté de Paris, et Dr. CYRILLE JEANNIN, Chef de Clinique adjoint à la Faculté de Paris. With 113 figures. Paris: F. R. de Rudeval. Pp. 736. Price 9 francs.—In preparing this work the authors have endeavoured to make it essentially clinical and practical in character. They have treated in especial detail the various methods of treatment and the different operative procedures recommended. Questions of less importance are discussed more briefly, but they are all duly considered and the work is a complete treatise on the art of obstetric medicine. It is divided into two parts: the first is concerned with the physiology of pregnancy, labour, and the puerperium, whilst the second deals with the pathology of these three conditions. The book is written in a clear and simple manner and the authors make frequent use of short paragraphs and tables. In many instances it is especially full, as for example in the section dealing with the care of premature infants, and it will no doubt prove of value to the students for whom it is written.

The Nutrition of the Infant. By RALPH VINCENT, M.D. Durh. Second edition, revised and enlarged. London: Baillière, Tyndall, and Cox. 1904. Pp. 321. Price 10*s.* 6*d.*—A review of the first edition of this work appeared in THE LANCET of March 19th, 1904, p. 808. In its present form we notice few alterations of importance although the author with an extended experience of the laboratory method of preparing milk mixtures is more strongly convinced than ever that this method is the best. As the result of employing so scientific and exact a method as that which Dr. Vincent relies upon in his practice and describes in his book this conclusion is exactly what was to be expected. By employing accurate formulæ and measuring the amounts of the various ingredients employed in the preparation of the milk mixtures it is possible to keep a systematic record of the dietary and of the results achieved. This is, we take it, the only rational means of gaining a progressive knowledge of the feeding of infants. It is not so important to have a perfect food as to have a useful experience of the best methods of employing the material with which we have to work. Those who employ haphazard methods and despise the so-called percentage method of feeding or, in other words, the use of weights and measures, are very unlikely to obtain uniformly good results, or even to advance in the clinical knowledge which is necessary for the satisfactory feeding of infants. They may, indeed, occasionally obtain brilliant results but there will be no uniformity in their achievements. Nevertheless we cannot help thinking that Dr. Vincent is too restricted in his dietetic resources and, further, that he is too severe on certain of the expedients employed by clinicians of great experience in the feeding of infants. For instance, he describes all sugars other than milk sugar as foreign bodies and he denies to carbohydrates a position among the foods, and, further, he seems to think that the boiling or sterilisation of milk deprives it of most of its virtues and that its use necessarily leads to rickets, scorbutus, or some other manifestations of malnutrition. As with laboratory milk so with sterilised milk, success or failure depends more on the manner in which it is employed than on the character of the milk *per se.* We imagine that few authorities would claim that sterilised milk was better adapted for the purpose of infant feeding than pure, fresh milk, but probably most people would consider that it has advantages over milk which is seriously contaminated by micro-organisms. In most respects, however, we consider that the views which Dr. Vincent has expressed in this volume are thoroughly sound; at any rate, he advocates a method which is capable of great refinement and nice adjustment, and one which is calculated to give progressively better results as the man who uses it progresses in clinical experience and in a knowledge of the practical applications of variously modified milks.

New Inventions.

IMPROVED HIGH POTENTIAL APPARATUS IN ELECTRO-THERAPEUTIC APPLICATIONS.

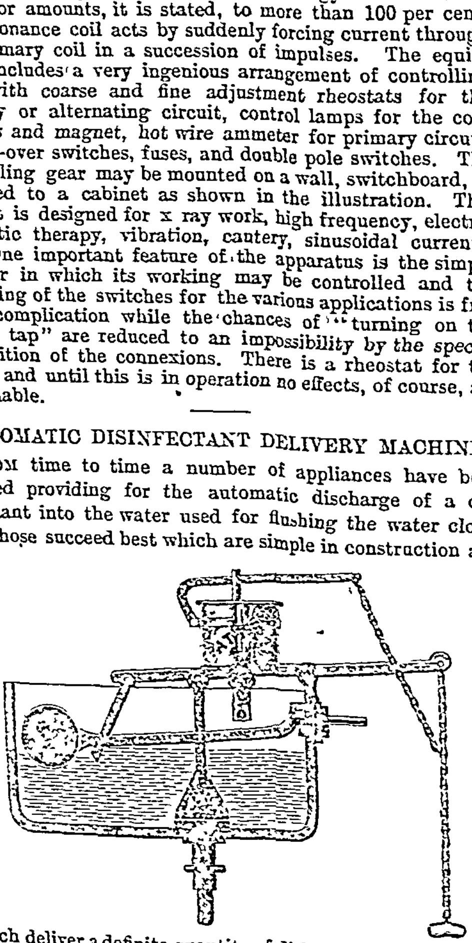
DAY by day further additions are made to the electro-therapeutic armamentarium and as the applications increase it is desirable that whilst the equipment should be comprehensive it should also be made as convenient and compact as possible. It would be a great gain, for example, if with one apparatus all the applications of the electric current—e.g., x ray work, high frequency currents, sinusoidal currents, vibratory massage and other mechanical work, and small lamps, cauteries and so forth—could be made. Further the apparatus should be available either with the continuous or alternating current from the main. An apparatus practically fulfilling all these requirements and occupying but a relatively small space was shown by Messrs. Isenthal and Co., of 85, Mortimer-street, London, W., at the recent conversazione of the Royal Society where it naturally attracted the interest of the medical visitors. The upper part of the apparatus, which is known as the Grisson resonance apparatus, is shown in the accompanying illustration. The reverser situated at the base of the



stats and switches and protected by a guard rail is in the form of a modified commutator with two slip rings upon which four brushes bear, those for ommutator being adjustable laterally and angularly. It riven by means of a quarter horse power semi-inclosed tric motor, a flexible coupling being interposed, and the d is regulated by a rheostat. The free end is fitted to flexible shafts for surgical instruments, vibrators, &c. reverser dispenses with the interrupter of the old action coil and has the very distinct advantages that it ks without sparking, contains no mercury to "sicken," no expensive platinum contacts to burn. The conser may be charged from one to 200 times per second, ing with the resonance coils anything up to 1000 sparks second between the terminals of the coil. The consers are situated in a cupboard (not shown in the ture) beneath the upper part of the apparatus and sist of two or more steel vessels fitted with a terminal. e lid carries two folded aluminium plates kept in position glass insulated uprights fixed to a false bottom in the cell such a way as to make short circuits an impossibility. e dielectric is only a minute fraction of a millimetre in ckness, being represented by a film of aluminium hydroxide med electrolytically on the surface of the aluminium ites. The electrolyte is a special alkaline solution. The pacity is enormously increased by adopting such an exmely thin separating dielectric. It exceeds for each connser 100 microfarads at a charging potential of 110 volts d 50 periods and will discharge on a 100-volt circuit at a te up to 15 ampères through the coil. The resonance coil s no condenser and gives sparks up to 16 inches in length d of immense magnitude. The coil is said to be equal in ficiency to an ordinary coil of 28 inch spark-length worked ith an interrupter. The reserve of energy in the Grisson sonator amounts, it is stated, to more than 100 per cent. he resonance coil acts by suddenly forcing current through e primary coil in a succession of impulses. The equipent includes a very ingenious arrangement of controlling ear with coarse and fine adjustment rheostats for the rimary or alternating circuit, control lamps for the conensers and magnet, hot wire ammeter for primary circuit, hange-over switches, fuses, and double pole switches. The ontrolling gear may be mounted on a wall, switchboard, or ttached to a cabinet as shown in the illustration. This abinet is designed for x ray work, high frequency, electromagnetic therapy, vibration, cautery, sinusoidal currents, c. One important feature of the apparatus is the simple nanner in which its working may be controlled and the operating of the switches for the various applications is free rom complication while the chances of "turning on the wrong tap" are reduced to an impossibility by the special disposition of the connexions. There is a rheostat for the motor and until this is in operation no effects, of course, are obtainable.

AUTOMATIC DISINFECTANT DELIVERY MACHINE.

From time to time a number of appliances have been devised providing for the automatic discharge of a disinfectant into the water used for flushing the water closet and those succeed best which are simple in construction and which deliver a definite quantity of disinfectant each time the flushing cistern is emptied. The merit of simplicity as well as efficiency certainly belongs to the apparatus of the Automatic Disinfectant Delivery Machine Company, Limited, of 2 and 4, Tudor-street, London, E.C. The manner of working of the apparatus will readily appear from the accompanying illustration. A small metal container is fastened by means of a thumbscrew to the top of the cistern. A valve in this container is operated by a chain attached to the chain of the cistern itself. When the cistern chain is pulled the valve of the disinfectant container is opened and a measured volume of the fluid is released which, mixing with the flush, provides an effective disinfecting "wash down." It is a decided advantage also that the method leaves in the trap and pan a quantity of disinfecting fluid so that any return gases that may escape would be submitted to the action of the disinfecting agent. The fluid used in the model with which we made a practical trial appeared to consist of an alkaline mixture of phenols and pine oil but obviously any other fluid may be used for the purpose. The disinfectant container, of course, requires to be filled at intervals, but for ordinary purposes it holds sufficient disinfectant for a month's use. Assuming that the addition of a disinfectant fluid to excreta is desirable, this plan seems to be a very convenient and satisfactory way of effecting that end.



MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER XIX.[1]

The Amendment of the Medical Acts.

The Constitution of the General Medical Council.—The One-Portal System.—The Legal Prohibition of Quackery.

Medical organisation, however perfect, and public opinion, however sympathetic, will not accomplish the removals of all the evils that have been displayed. They would do a great deal and would pave the way for more but the law of the land expressly permits a state of things which cannot be altered by any united effort on the part of medical men, be it ever so kindly received by the people. As long as there are over 20 ways of entering the medical profession so long will there be a certain amount of disorder in medical education and jealousy in the ranks of medical practitioners; and as long as the only existing legislation against quackery is limited to the imposition of a small fine for falsely pretending to be a medical man, so long will the charlatan, run riot amongst us. As both the disorderly condition of medical education and the impunity of quackery depend upon the wording of the Medical Acts it is not surprising that all medical reformers have put in the front of their programme the amendment of these Acts. The suggested amendments are usually as follows: (1) the alteration of the *personnel* of the General Medical Council so as to make it a more representative body; (2) the institution of one State examination by which the medical profession must be entered; and (3) the legal prohibition of medical practice by persons not registered as medical men. We may consider the amendments in that order.

1. *The Alteration of the Personnel of the General Medical Council.*

The General Medical Council, as the Council is at present constituted, is not representative of the medical profession. It has been generally assumed that, if its constitution were altered until the Council was more representative in character, its deliberations would be of a more practical sort, while, its intimacy with the troubles of the general practitioner being greater, it would be more capable of bringing public needs into line with medical service and of interpreting professional views so that laymen would recognise their justice. These things and more have been assumed on apparently good grounds, but it must be remembered that until a reconstituted Council has actually taken over the work to be done assumption is all that we have to go upon.

---

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII. XIII., XIV., XV., XVI., XVII., and XVIII. were published in The Lancet of Feb. 18th (p. 447) and 25th (p. 517), March 4th (p. 593), 18th (p. 736), and 25th (p. 817), April 1st (p. 877), 15th (p. 1017), 22nd (p. 1089), and 29th (p. 1151), May 6th (p. 1218), 13th (p. 1287), 20th (p. 1375), and 27th (p. 1449), June 3rd (p. 1533), 10th (p. 1584), 17th (p. 1651), and 24th (p. 1741), and July 1st (p. 43), 1905, respectively.

The General Medical Council is at present made up of 32 persons, five of whom (three for England and one each for Scotland and Ireland) are elected by the registered practitioners resident in the different countries, four of whom are nominated by the Crown, and 22 of whom are chosen by the governing bodies of the 22 universities and corporations the medical tests of which admit to the Register. The universities and corporations enjoy, therefore, a very powerful position. In many directions their interests must be identical, and where those interests clash with the interests either of the medical profession at large or of the public an effective combination could be made to uphold the teaching bodies. Such an abuse of position is not as likely to occur as some would have us believe, but the question is whether it can be made a complete impossibility. The numerical ratio of Crown members and direct representatives to that of the representatives of the universities and corporations can be raised either by adding to the former or subtracting from the latter. But there are valid objections to either course. The General Medical Council is in the opinion of good judges, persons who are, or who have been, influential members of the Council, too large already. The deliberations of the Council are hampered by its size and the expense of the sessions is increased. But to take away from any of the universities or corporations their right to a representative is a serious step. The British Medical Association has prepared a Bill for amendment of the Medical Acts in which this course has been adopted in a drastic manner. The examining bodies are to send only nine representatives instead of 22. The University of Oxford and the University of London, the University of Cambridge, and the University of Birmingham, Trinity College, Dublin, and the Royal University of Ireland, the University of Edinburgh, and the University of St. Andrews under this scheme are to be bracketed together and alternately disfranchised, while the representation on the Council of the corporations is to be curtailed still more rigidly. The number of direct representatives is to be increased from five to eight and a dental representative is to be added. In this way the *personnel* of the Council is changed from 32 to 23, while the representatives of the examining bodies can be put in a minority by unanimous action on the part of the Crown members and the direct representatives. The attempt to reduce the numbers of the Council so made is a brave one but the deprivation of certain examining bodies, though only temporarily, of their votes is a step so serious that it must certainly provoke opposition. To take the educational function of the General Medical Council into consideration alone, it would be clearly inadvisable that a debate should be held upon the educational standards of a university or a corporation without there being present at the Council table a representative of the body in question. On the other hand, to increase the General Medical Council until a combination of the representatives of the examining bodies could not outvote the rest of the Council would mean adding 12 more members at least as Crown representatives or direct representatives. And addition could not end there, for the examining bodies tend to increase in number—the University of Birmingham, for example, obtained a representative in 1903 and Liverpool one in 1904, while the University of Wales, the University of Leeds, and the University of Sheffield will presumably have the same privilege granted to them shortly. Each such addition must be counterbalanced if the chance of abuse of power on the part of the educational bodies is to be removed, and the Council would tend to become in the end an unwieldy body.

The difficulties involved in alteration of the numbers of the Council have led to the suggestion that the medical profession as a whole might be more adequately represented upon the Council if the representatives of the qualifying bodies were chosen by the vote of the members of the corporations, or by the medical graduates of the universities, instead of being delegates from the respective ruling bodies of the universities and corporations. Undoubtedly if the representatives of the educational bodies were chosen by the votes of the constituency at large the general practitioner would feel himself much more fully in touch with the disciplinary body of the profession. He would have a vote for the election of his own representative, which is in accordance with all popular notions of reform, but there is none the less a good deal to be said against the idea. The university graduates (at any rate an ascertainable portion of them) do not ask for the privilege of voting for their representatives on the General Medical Council, while the charters of the corporations appear to vest the power of appointment of a representative on the Council in their governing bodies. Before the reform can take place these charters must be abrogated. Again, elections are a weariness to the voters, as is shown by the small number of medical men who register their votes at the comparatively infrequent elections for direct representatives on the General Medical Council. Elections also impose much trouble and annoyance upon candidates and it would not be easy in all instances to secure the candidature of the best man, because he would not care to submit himself to the worries and personalities of an election. It may be all in a day's work for a politician, but a medical man is not inured by his professional life to being called, even by implication, a time-server, an anarchist, or an idiot, which might be the fate of any candidate who happened to seek election to the General Medical Council at a time when medical opinion was divided and feelings were running high. We have only to refer to the incidents of the election for direct representatives in 1901, when the registration of midwives was on the *tapis*, to feel certain of this. A large section of the medical profession at the time was bitterly opposed to the suggested legislation and the amenities of debate were considerably strained by the champions of either side. This acrimony could again be caused by the public discussion of many topics of politico-medical or ethico-medical interest and a series of elections might come to mean a series of rows. Besides it is, to say the least, doubtful whether the medical profession would be better served if the representatives of the various examining bodies were to be selected by the whole constituency. Such a body as the Council of the Royal College of Surgeons of England, for example, is sure to be represented under existing methods by a tried and capable official—a past examiner familiar with educational theory and routine, a man who can carry weight among his colleagues on the General Medical Council. His qualities are known *au fond* by the Council of his College before the interests of the College are confided to him. But if the Fellows and Members of the Royal College of Surgeons of England, a constituency of 18,000 persons, were allowed to select one man among them as a representative the chances of their choosing the man who asked most urgently for their suffrages and who was most prolific of promises would be great. And similarly great would the chances be that such a representative would turn out a failure on taking his seat at the Council board. I have selected the Royal College of Surgeons of England as an example, because it is a very large constituency, numbering over 18,000, governed by a very small body which, in its turn, is elected by an upper class numbering about 1200—that is to say, that 17,000 Members of the College have no voice in the election of their representative on the General Medical Council either directly or indirectly.

There is a way out of this position. The Council which chooses the representative might itself be elected by the 17,000 Members and not by the 1200 Fellows—a liberal development that has for three-quarters of a century been urged by THE LANCET. And in a similar way the General Medical Council might be liberalised throughout. The Council of the Royal College of Surgeons of England is understood to have no serious objections to the change of constitution by which it would itself become a representative body, and at one time a majority of the Fellows, who might be expected to wish to retain their constitutional prerogative, was actually in favour of the reform. THE LANCET aided the movement unceasingly and a decade ago it seemed that the Members of the College were in a fair way to obtain a share in the management of their affairs, but the untactful behaviour of a few "whole-hoggers" ruined the *entente cordiale* between Fellows and Members. Relations could be renewed again if the proper course were taken. This is a very suggestive fact, for if the governing bodies of the corporations were selected by the members of the corporations then the members would feel that representatives appointed to the General Medical Council by such governing bodies were really appointed by the corporations as a whole—that is, by themselves—and their confidence in the deliberations of the General Medical Council would be much increased. The change in the constitution of the General Medical Council that would be produced by the change in the election machinery of the various universities and corporations need not be great, but it would be a wise and good reform, because it would give the General Medical Council more the character of a popularly elected body. To proceed further in making the Council popularly elective would be to call n the members of the profession to go frequently to the tings, and this they would not do, nor is it certain that best candidates would seek their suffrages.

2. *The One-Portal System.*

Ve come next to the proposal that all medical men uld enter the medical profession after passing one te examination. The "one-portal system" has been ired ardently by some of the most liberal thinkers doing away with all possible opportunities that some dents may enjoy for entering the medical profession upon ier terms than their fellows; and the British Medical sociation has provided in its new Bill for a State examina- n to precede admission to the Register. The simple y of securing a one-portal system that would give isfaction to the medical profession would be for the ite to hold identical examinations in certain capitals and iversity towns simultaneously and to admit the successful ndidates to the Medical Register under the title of M.D., or least with the clearly specified right for each man to call mself "Doctor." As far as the public would be concerned medical men would then be equal, and any favour which a an enjoyed with the public would be due to his work and s character. Appointments would no longer be open only graduates of certain universities or diplomates of surgery certain corporations. Every candidate for a post could oduce, as additional evidence of fitness, any testamurs at he possessed, but the non-possession of them would bar man from competing. The London student, working in e splendid clinical field of the metropolitan hospitals with e elaborate scientific environment of a metropolitan edical school, when entering private practice would no nger find himself described as "not a real doctor" ecause he did not possess a university degree. All edical men would be equal in the eye of the public nd the substantial grievance under the present *régime*, hat of two equally well-informed men one has and e other has not an academic right to the popular title f "Doctor," would disappear. Is there anything to be said gainst so simple a reform, so sure a way of making edical education uniform, so obvious a way of avoiding a ultiplicity of examinations, so complete a way out of the ifficulties that have arisen from the use of the word "Doctor" s a popular style as well as an academic title? Unfortu- ately, there is another side to the question; the institution f a State examination to the medical profession would robably be opposed by the medical corporations. The Universities might have nothing to say against the immediate doption of such a system but the corporations would be likely to take an opposite view. A student commencing his medical career at a university would naturally desire to graduate in medicine at that university. He would pass any examination additional to the State examination and pay any fees additional to the State fees, so that he might receive the hall-mark of his *alma mater*. But the student not entering the medical profession by way of a university, having passed the State examinations in medicine, surgery, and obstetrics, and having obtained a place on the Medical Register with the right to style himself "Doctor," would have little inducement to seek from a College or a Hall any Diploma? The honour diplomas or fellowships might still command candidates, but the rank and file of the medical profession would hardly consent to pay fees for pass diplomas when they already possessed the legal title of "Doctor." The corporations would probably suffer considerably, so that a one-portal system would have far-reaching consequences of a sort that must provoke opposition. And very awkward opposition, too, for the presidents and office-bearers of the Royal Colleges have a way of being the friends as well as the medical advisers of those who make the law of the land, and an amendment to the Medical Acts which the Royal Colleges decided to oppose would have but small chance of becoming law. A final examination of all students, wherever educated, for the right to a place on the Medical Register with the title of "Doctor" has so long been the conception of the reformer that the idea cannot be given up without reluctance; indeed, it should not be given up altogether, but those who hope for it will surely have to exercise patience, for no such reform will immediately be granted.

3. *The Legal Prohibition of Medical Practice by Persons not Registered Medical Men.*

Such a prohibition would be to do away with the impunity now enjoyed by quacks and would necessitate an alteration of the Medical Acts of a decided sort. The Medical Act of 1858 in its opening clause says that the Medical Register is to enable the public to ascertain who is and who is not a *bonâ-fide* medical practitioner, but it leaves the public to choose between the qualified man and the quack, merely supplying the necessary information so that the choice need not be made blindfold. The State recognises nothing but the qualified man. Only he can give a death certificate, or medical evidence, or express a medical opinion of any sort that will carry legal weight. But anyone in this country can practise medicine and practise it for gain; the law will only interfere with a man who says he is a registered medical practitioner under the Act when he is nothing of the sort, or who pretends to have a legal position as a medical man. The amount of that interference is shown by Clause XL. of the same Act, which runs as follows:—

> Any person who shall wilfully and falsely pretend to be or take or use the name or title of a physician, doctor of medicine, licentiate in medicine and surgery, bachelor of medicine, surgeon, general practitioner or apothecary, or any name, title, addition, or description implying that he is registered under this Act, or that he is recognised by law as a physician, or surgeon, or licentiate in medicine and surgery, or a practitioner in medicine, or an apothecary, shall, upon a summary conviction for any such offence, pay a sum not exceeding twenty pounds.

It is quite clear that almost no one will ever be convicted under such a clause. An irregular practitioner has only to tell the public that he belongs to no benighted medical corporation, but is practising upon some eclectic system of his own, to escape all penalty for his action. This position ought to be altered and as public appreciation of science grows it will undoubtedly be altered; but before Parliament will sanction reform it will have to be clear to the country that restraint upon quackery is called for on public grounds. Medical men naturally, but unfortunately, have been in the habit of regarding everything in the nature of medical treatment by unqualified persons as so productive of evil that they have a little blinded themselves to the fact that their fellow-men are free agents, free to ask whom they like to treat their bodies or their souls. A man need not belong to the Established Church because he happens to be an Englishman, nor need he employ a registered medical man. This must not be forgotten nor must the effect of coercion be disregarded. Any attempt to make it illegal to employ unqualified men might lead to a still larger employment of them, for the public would consider the restraint imposed upon it intolerable. Members of the public have a right to consult whom they like when they are sick, even no one at all if it is they themselves who are sick and not their infant children. Yet there are good grounds for Parliament interfering with the present unbridled liberty of unqualified practitioners and it is certain that the wiser sort of the community would welcome an attempt to do so. The misery that is wrought by quacks, the lives that are sacrificed by their lust for gain, the false hopes that are inspired by their advertisements, the hard-earned money that is wasted upon their rubbish,—all these make it necessary in the public interest that a check should be put upon the nefarious practices of charlatans. In the Medical Acts Amendment Bill, prepared by the British Medical Association, there is a clause to meet the situation, which runs as follows:—

> *Penalty for practice by unregistered persons.*—Any person who is not registered under this Act and who medically treats patients, or otherwise practises medicine, surgery, or midwifery, or performs any surgical operation for which he demands or receives any fee, gratuity, or remuneration, and also any person who not being registered under the Act, pretends to be, or takes or uses the name or title of physician, or surgeon, doctor of medicine, licentiate of, or bachelor of, medicine or surgery, or master in surgery, or assumes any other style, title, addition, designation, or description, either attached to the name of the person or to his place of residence or business, or otherwise exhibited, implying that he possesses the skill and knowledge necessary for the practice of medicine, surgery, or midwifery, or that he is recognised by law as a physician or surgeon or licentiate, in medicine or surgery or midwifery, or a practitioner in medicine, or an apothecary shall be guilty of an offence under this Act, and shall on summary conviction under the Summary Jurisdiction Acts be liable (1) for the first offence to the penalty of not less than ten and not exceeding twenty pounds, and to imprisonment in default of payment of not longer than two calendar months; and (2) for each subsequent offence to a penalty of not than less twenty and not exceeding forty pounds, and to imprisonment in default of payment for not longer than six calendar months.

With this clause every medical man must be in accord, and members of the public who have realised the real dangers of quackery, its horrible menace to public health, its extraordinary depletion of the public purse, should take the same view. The clause wants certain modification, as it must be made quite clear that the ministrations of the neighbour, the nurse, or the masseur are not illegal, but with this alteration it would serve the purpose of protecting the public. It would not stop quackery, for while men are greedy there will be disgraceful advertisements and the money of the public will be divided between rogues and the proprietors of unscrupulous newspapers. But this scandal would be lessened if the complete impunity of the quack were lessened. The chances of fine and imprisonment would give pause to the quack desiring to claim openly "that he possesses the skill and knowledge necessary for the practice of medicine, surgery, or midwifery," and editors could not plead convenient ignorance concerning convicted quacks when the propriety of an advertisement was called in question.

But though an amendment of the Medical Acts which should prevent quackery is called for, and although to many medical men the call seems particularly loud and clear, no legislation is likely to occur without opposition. Parliament in its dislike to the appearance of granting a monopoly to any class, will require much persuasion, and even here there is wanting the unanimity of voice among medical men, the lack of which has been noted as standing in the way of so many reforms. Legislation against quackery appears to some of the most enlightened members of the medical profession unnecessary and undesirable as savouring of an undignified protection of true science. More than half a century ago, when the question of making unqualified practice illegal was being discussed, Sir Benjamin Brodie spoke strongly against the view. He urged that the medical profession should stand or fall upon its merits and did not require any legal protection. Things have changed for the worse since Sir Benjamin Brodie's time, yet we know that even then quackery was rampant. The dignified attitude that this great surgeon took up is one that many medical men will be found to adopt to-day, and even legislation against quackery will not be pressed upon Parliament with the complete unanimity of the medical profession that might have been expected.

While the majority of medical men, at any rate of those who give heed to the public relations of medicine, are in favour of amendments to the Medical Acts on the lines that have just been discussed, it must be borne in mind that no legislation is likely to occur without considerable struggle. The reasons for the alteration of the constitution of the General Medical Council are not incontrovertible, while no alteration, it would seem, can be suggested that will not give rise to some friction among the bodies to be represented, and so prevent that unanimity of view that the public will almost require of the medical profession before it will give support to any amendment of the Medical Acts. The institution of a State doctorate, though so desirable a reform, can hardly take place without seriously damaging the various medical corporations. Anything like drastic prevention of quackery by law, though this would mean a saving in lives and money to the nation of many thousands of pounds annually, is sure to be resisted strongly when it is mooted in Parliament.

These things must be remembered and the difficulties ahead should make medical reformers additionally anxious to be unanimous in their aims.

(*To be concluded.*)

THE MEDICAL CURRICULUM.

Mr. John Tweedy, the President of the Royal College of Surgeons of England, speaking at the prize-giving at the Medical School of Westminster Hospital on June 28th, drew attention to the present condition of the medical curriculum and observed that there was danger sometimes in over-rating mere academic successes during the student's earlier life. After all, the medical profession required the power of doing something and successes in class examinations might only imply a power of acquiring knowledge. Knowledge and power, he need scarcely tell them, were two very different departments of life. Knowledge was not even synonymous always with wisdom. Many of them, no doubt, would remember Cowper's lines:—

> "Knowledge and wisdom, far from being one,
> Have oft-times no connexion. Knowledge dwells
> In heads replete with thoughts of other men;
> Wisdom in minds attentive to their own."

When a student came to a medical school very often to his surprise, instead of beginning, as he imagined, the practical study of his profession, he found that he had to encounter several so-called preliminary sciences—chemistry, physics, and biology—before he could begin what are known as the early medical subjects of anatomy and physiology. That arrangement had been forced upon them by the kind of patchwork legislation that had been going on in the medical curriculum during recent years. If he were to criticise the medical curriculum he believed he would have the sympathy of a good many of those present when he said that the first thing he should like to see in it was a great simplification. So far from adding bit by bit to the burden which the student nowadays had to bear, he would take off a good many of the subjects which were now put upon the over-burdened student, taking care that he had more time for the thorough training of his faculties and the training of his powers of observation, instead of merely converting himself into a grinding machine in order to pass examinations. The teaching of these preliminary subjects in medical schools connected with hospitals had stood in the way, for some time, of the best medical education and he congratulated the authorities of Westminster Hospital on being the first to complete the arrangements for removing the teaching of those *preliminary subjects from a medical* school and arranging for the students to study those departments of natural science at a science institution. That was good, he was sure, for the medical students and it was good for medical education. The practice of medicine was largely one of applied science, and it was but right that those who were about to enter upon the medical profession should be trained in scientific methods. Those methods could best be taught in great scientific institutions. So long as the teaching of those preliminary sciences was kept in the medical schools one could not but feel that their importance as disciplines of the mind was somewhat lessened. On the other hand, the men who learned physical science in a great science centre benefited by great traditions and they acquired the best methods of observation and of reasoning. The student's scholastic training was generally a literary training, a training in which authority counted for everything; but in sciences authority counted for nothing except so far as it was based upon accurately observed data. That was one of the great benefits which medical education would derive and medical students would *gain from eliminating those preliminary* sciences from the medical course of studies at a hospital. Assuming that the student had completed his preliminary science training and had also completed those earlier medical studies, such as anatomy and physiology, upon the importance of which it was unnecessary for him to dwell, he then came to the great work of his life, the study of disease in the wards of the hospital, and he insisted that it was the work done in those wards that determined a man's career. An experiment was to be tried at Westminster Hospital in regard to the lectures to be delivered there. Instead of having the whole course of lectures on systematic medicine or systematic surgery given by one man it was proposed to break up those subjects and to intrust to different members of the staff different subjects. That was an experiment for which much might be said and it was an experiment which he should watch with a good deal of interest. He hoped, however, that in that arrangement there would not be neglected what he thought was necessary in all studies —a sort of propædeutic or introductory course expounding the great principles of medicine and surgery. If that were done he thought the experiment of handing over the several departments to experts might be successful. Otherwise he feared that it would lead rather to too early specialisation. Students were prone to think that medicine was so rapidly progressive that knowledge soon became obsolete, but the knowledge which students would acquire in the wards of the hospital during their course of training would be the basis upon which they would have to build the whole of their practice in the future. Knowledge grew, but truly and carefully observed phenomena did not change. Their conceptions had to be changed, their explanations of phenomena had to be readjusted, their theories often had to be recast entirely, but the fundamental problems of knowledge remained the same. If the clinical cases which might come under their observation were observed by them without prejudice they would constitute the true foundation of their knowledge and remain as the working capital of the whole of their subsequent lives.

THE LANCET.

LONDON: SATURDAY, JULY 8, 1905.

The Romanes Lecture: "Nature and Man."

THE title selected by Dr. RAY LANKESTER for his lecture the Sheldonian Theatre at Oxford is one which must vitably attract the attention of members of a profession cerned in daily observation of problems presented by Nature and Man." That the subject should be approached h some degree of vehemence will cause no surprise; Dr. Y LANKESTER has on many former occasions demonstrated power of expressing his views with an energy which nost challenges contradiction, since it betrays a strong rtisan spirit with an air of intolerance, doubtless accintal and unintentional, for the opinions of those with iom he differs. Most medical men must be credited th convictions about the true relation of nature to man d yet may hesitate to follow the line of argument in this cture or to express entire concurrence with its logical conusions. In contradiction of POPE's dictum that the proper udy of mankind is man we are presented with an altertive study of nature as comprised in physics, chemistry, ology, and biology. It might be hastily considered that r. RAY LANKESTER, *speaking* on such a theme, would giving us the shoemaker's view of the value of leather it this would be an injustice to the amount of thoughtful gument displayed in the course of the lecture. Dr. RAY ANKESTER believes that "the time has arrived when the ue relation of nature to man has been so clearly ascertained iat it should be more generally known than is at present ie case, and that this knowledge should form far more rgely than it does at this moment the object of human ctivity and endeavour—that it should be in fact the guide of tate Government and the trusted basis of the development human communities." He employs the word nature as a ame for the "entire mechanism of the universe, the kosmos all its parts," and he maintains that man has attained n extraordinarily complex control of the conditions in which is life is carried on. While man is a part of nature, a roduct of the definite and orderly evolution which is niversal, he is driven by the relentless mechanism which we all nature, and "it is his destiny to understand and to ontrol it." This view seems rather revolutionary; it almost epresents man as a child who, having learnt to some extent iow the wheels go round, is to be encouraged to attempt to egulate their action or even to try to produce new results y interfering with the works.

There can be no doubt that man has not been content to remain a passive spectator, that his will or olition has become a power in nature, which has proundly modified not only his own history but that of the whole living world and the face of the planet on which e exists. That man is to be regarded as "nature's rebel" is shown by reference to recent progress, to the immensely increased facilities in the application of mechanical power, in locomotion, in agriculture, and in endless arts and industries; and, on the other hand, equal progress has attended measures which he has adopted for the relief of disease and pain. The primary lesson which must be learnt from a consideration of any scientific history is that there is no finality—no stage at which it is possible to rest content with past achievements. The march of progress is endless and relentless. Dr. RAY LANKESTER asserts that civilised man, in his rebellion against natural selection and his defiance of nature's pre-human dispositions, has produced such a special state of things that he must either go on and acquire firmer control of the conditions or perish miserably by the vengeance certain to fall on the half-hearted meddler in great affairs. He is threatened on every hand by dangers hitherto restrained; no retreat is possible; the only hope is to control the sources of these dangers. The section of Dr. RAY LANKESTER'S address dealing with disease is one replete with interest, serving to present many familiar facts in a new light, and for the benefit of medical readers we may say that the address has been issued as a pamphlet. While nature eliminates those diseased or liable to disease man continually rebels and endeavours to prolong life. From the standpoint of the biologist the congenitally diseased are destroyed, as far as race development is concerned, before they can reproduce; parasites either carry off the congenitally weak (and thus strengthen the race) or become harmless by the survival of individuals capable of tolerating attacks without injury, and so we have the establishment of immune races. It is asserted that with few exceptions every disease to which animals are liable is due to man's interference. By treating disease man staves off the "adjustment by death" and thus accumulates vast populations of unadjusted human beings, animals, and plants which from time to time are ravaged by disease. This fact affords no material for discouragement to Dr. RAY LANKESTER but forms the immediate prelude of the cheering statement that the knowledge of the causes of disease is so advanced that it is practically certain that by the application of methods of investigation and consequent controlling action "all epidemic disease could be abolished within so short a period as 50 years. It is merely a question of the employment of the means at our command." We should not have ventured to go so far ourselves but undoubtedly it would be as bad to set a limit to what might be effected by the diligent application of the results of pathological research as it is to prophesy immediate and sweeping issues from the same. But unless the work of research is definitely encouraged at our seats of learning and education these results will not produce any great revolution. And it may be freely granted that Dr. RAY LANKESTER is right in holding that research is discouraged in this country by the comparative lack of State recognition and financial support. If more men and abler men were employed in study and experiment better results would be obtained in a shorter time, and these results would be of "greater significance to mankind than the emendation of a Greek text or the determination of the exact degree of turpitude of the statesmen of a bygone age." The supersession of the classical and historical scheme of education by a scheme of education in the knowledge of nature is Dr. RAY LANKESTER'S suggestion for our future guidance and he advances his views with characteristic vigour and wit. Scholars in history and adepts in classics will not think him fair or unprejudiced, while many—and among them many medical men—will see no possible objection to the immediate adoption of his views, so that the excitement created by the Romanes Lecture of 1905 was to be expected.

The knowledge of nature intended by the lecturer had already been defined as that comprised in physics, chemistry, geology, and biology, subjects which, with the exception of geology, now form part of the training of medical students, and Dr. RAY LANKESTER believes that every man of even a moderate amount of education should acquire a sufficient knowledge of these subjects to enable him to appreciate their value and to take an interest in their progress and application to human life. Those who have watched the study of natural laws by medical students are not in unanimous agreement with this view. Perhaps it will be argued that the poor results of the instruction of medical students in natural science are due to the novelty of the subjects and to the lack of adequate previous training. Still, what now happens in the case of medical students might well happen, at any rate for some time, among all students if a course of instruction in natural science became compulsory. There might be great danger in the possession of a mere smattering of scientific jargon by the man in the street, and it must not be forgotten that with no classical training scientific terminology is likely to cause grave difficulties to the average schoolboy. While we should gladly welcome public measures producing a greater number of scientific workers, it may be well to maintain an open mind as to the value of wholesale change. It is impossible to expect that every schoolboy is in future to be trained as a scientific investigator, though it is desirable that greater encouragement should be afforded to those with scientific aptitude. Dr. RAY LANKESTER is to be congratulated on the courage with which he has advocated his views in his lecture. It may be feared that his references to classical and historical studies are not likely to be of much service to the advancement of science, and the assertion that the University of Oxford is exercising an injurious influence upon the education of the country does not seem to us warranted. Already there is a scheme for the development of technical science by the formation of an Imperial College of Applied Science in London but this is not antagonistic to the classical and historical schemes of education associated with the older universities.

The Prevalence of Cancer.

THE question as to whether cancer is increasing amongst the population is one which is continually being raised, both by the public and by members of the medical profession. The recent discussions which took place at meetings of the Life Assurance Medical Officers' Association demonstrated that some difference of opinion on this point still exists even amongst those who have given a large amount of thought and time to the subject. An answer can unfortunately only be given by the study of statistics. Such a method is generally acknowledged to be liable to fallacies and various speakers pointed out the errors that may arise in the different courses which have been adopted in the endeavour to arrive at the truth.

The discussion was opened by Dr. W. S. LAZARUS-BARLOW and Dr. GORDON TAYLOR who had prepared a paper entitled "The Evidence yielded by the Statistics of the Middlesex Hospital on the Question of an Increase of Cancer." An ingenious plan of obtaining statistics had been adopted. If a person dies in a hospital at the age of, say, 50 years, the actual year of his birth can be deduced from the year of his death. Therefore, if the post-mortem records of a hospital over a number of years are examined and each case is marked on a previously prepared sheet under the year of his birth a population is created by working backwards from the deaths of individuals. By this means, the authors of the paper maintained, it was possible to ascertain whether the proportion of deaths from cancer during a certain period had increased or otherwise. Several fallacies in the method were pointed out, not only by Dr. LAZARUS-BARLOW and Dr. GORDON TAYLOR, but also by subsequent speakers. From the very nature of the case it is clear that the results deducible from these statistics cannot be directly applied to the entire population. The class from which a general hospital draws its patients is insufficiently representative of the entire community. The patients are to a certain extent selected and we think that it may fairly be urged that especially is this the case at the Middlesex Hospital. In this institution there is a wing entirely devoted to cases of cancer and thus there is a probability that a larger proportion of such cases would be admitted in contrast to other cases than would be found amongst a similar number of individuals amongst the general population. Nevertheless, these statistics are of great interest and at any rate they show what is the experience of this particular hospital. A similar examination was made of the records of St. George's Hospital. At both hospitals it was found that from the time at which the statistics were first calculated (about 1830) to about the year 1870 there was an increase in cancer amongst women and a stationary high level had been maintained from that time to the end of the century and at both hospitals there had been in men a steady increase of cancer from the earliest date (1830). From a further investigation it was concluded that the increase in cancer was somewhat intimately associated with the alimentary tract in both sexes. Dr. J F PAYNE was also of opinion that the number of cases had increased in recent times and he agreed that a great part the increase was due to malignant disease of the digesti tract "from one end to the other," basing his opinion up the statistics of the Registrar-General for England Wales and for Ireland respectively Dr. A. NEWSHOL expressed his belief that there was no trustworth evidence of a true increase in the rate of m tality from cancer. He did not, however, state grounds upon which his opinions were founded. admitted, on the other hand, that the disease causes high mortality in all civilised countries. He pointed that in England cancer is reputed to cause, according to returns of the Registrar-General, a mortality of about 0·8 1000 of the population. He further stated that he consider that this figure is an under-statement of the real facts that when a more complete registration of all the dea vhich are due to malignant disease is established it will found that the deaths will be at least 1 per 1000 of population and judging by some local returns in his session he feared it might be as high as 1·2 per 1000. The neral opinion expressed in the course of the discussion was cidedly in favour of the view that during recent times ere has been an increase in the mortality from cancer. r. R. HINGSTON FOX, however, drew attention to the signiant remarks to be found in the second report of the nperial Cancer Research Fund. In this report no definite ew is expressed on the point which we have been discussing ut it is intimated that the extent to which cancer is ecorded is inversely proportional to the difficulties which ave to be overcome in obtaining information. Therefore he conclusion is reached that the data at present to hand re not sufficient upon which to form an opinion as to the lleged increase of malignant disease. The whole subject nust be *sub judice* but satisfaction may be felt in the nowledge that the last report of the Cancer Research Fund, is will be seen by reference to another column of this ue (p. 104), shows that researches are being undertaken hich may at any moment end in definite results.

Before concluding we may draw attention to another point hich was raised by Dr. HINGSTON FOX in the discussion—amely, as to whether the taking of alcohol has any influence producing cancer. Great difficulty must naturally be xperienced in investigating this question, but the evidence dduced from the death claims of life insurance offices is oubtless of considerable value. Dr. NEWSHOLME referred o statistics which he had published[1] based on three years' xperience of the United Kingdom Temperance and General Provident Institution, a large society which has two completely independent experiences, that of abstainers and that of non-abstainers. Without going into detail he stated that it was found that the death-rate from cancer amongst the abstainers was 0·95 per 1000, and amongst the non-abstainers it was 1·34 per 1000. In other words, if the death-rate from cancer amongst non-abstainers be taken as 100, it would be 70·9 amongst abstainers, or 29 per cent. less. Dr. HINGSTON FOX urged that further support of the relation of the use of alcohol to the increase of cancer was to be found in the frequency with which the disease attacked the digestive organs, suggesting that alcohol might have some deleterious local action on the mucous membrane of the stomach and the intestines. These remarks cannot be accepted as more than suggestive. It would be rash without further evidence to conclude that there is an etiological relationship between alcoholism and cancer.

◆

Pathology in the Streets.

IT is the medical man's privilege or penalty—for he may regard it either way—that his profession is always with him, and that whether he will or not he must needs view his fellows with something of the critical attitude that he adopts towards his patients. He is always, so to speak, on sentry go, and cannot, like the majority of professional men, emerge at will from the beaten path of his life-work. The solicitor may rise from his desk, shut away his documents, and leaving his office tread the streets in entire forgetfulness of the particular education that earns him his bread. The medical man cannot do this. Even if he be heedless in a general way of what goes on around him, still he remains an observer from the point of view of his own science. This is the groove that the nature of his calling has planned for him and he cannot escape it, however much he may be at leisure. It was half-way to this standpoint that CARLYLE in his "Sartor Resartus" would have led the academic mind, but only half-way, since the medical man's eyes look out upon a humanity, not merely stripped of clothes, but displaying its vital organs to his inspection. The medical man must to a larger or less degree remain the pathologist in the streets. It is, as we have said, doubtful whether this is a privilege or a penalty. But the medical man is seldom a sentimentalist in the accepted sense of the word; and the unsuspected tragedies which unfold themselves before him are well enough balanced by the compensations that smooth their path and the comedies that rub shoulders with them on either side. SHERLOCK HOLMES owed both his prototype and his creator to the ranks of the medical profession and if we recollect rightly his powers detected as many innocents as criminals. And it is just this balance that saves the medical man's peace of mind from any morbid result of his instructed vision.

That there is a grim side to the question cannot be denied, for to the medical man more than to any man superficial appearances are no disguise at all. To him the pathological truth becomes apparent, even in the briefest journey, sunning itself on the pavement or hurrying, bag in hand, to railway station or crowded mart. The medical man is on nodding terms with death at most street corners in our larger towns, and if he were called on to prophesy his knowledge might well make him a very JEREMIAH among his fellows. For who else would suspect the sword of DAMOCLES that is hanging above this red-faced merchant or see in his cheeks the signal of a fruit overripe? To the lay mind this portly person stands for all that is prosperous and confident, and his appetite is the envy of many of his dyspeptic friends—who will send wreaths to his funeral. See the bluff and kindly manner with which he hands his shilling to a thin-faced woman selling bootlaces in the gutter. It is only the medical man who would dare to prophesy white hairs for her long after her benefactor has been gathered to his fathers. There may be no great tragedy in this. There is more, perhaps, behind some sunburnt cheeks that make all these other jostling faces look pallid and worn by contrast. The layman glances curiously at them and covets their brown-red hue; the medical man is quick to recognise the imprint of the health resort, other things pointing to an ominous diagnosis. There are other instances where disease is rather suggested than revealed by the appearance of its owners, cases where the medical man cannot help suspecting the presence of a cirrhotic liver, granular kidneys, and the like. These are the cases that do not obtrude themselves upon the average man in the street and form the group that, according to his humanity, makes the medical man pay the highest price for his wisdom. But in the more obvious pathological lesions he begins to discover its solace. For here he becomes able to judge, as no other man can, of their relative significance. He does not share the pity that runs through the crowd as some chalk-faced patient, with his arm in a sling, walks slowly and painfully along the pavement, for his prophetic instinct shows him this same man, two or three months hence, wielding a spade or hunting four days a week, leading, in fact, a perfectly healthy physical existence in accordance with the sphere in which he lives. On the other hand, the woman with the curious red spot upon her face, half hidden by hair and a veil, affords him a far more sombre chapter for reflection. For whether it be lupus, or epithelioma, or a rodent ulcer, and whether it be treated or not, it will have meant, when these same months have passed, a far greater obsession of bodily and mental pain than that of any broken limb. Such cases as these are fairly balanced and the medical man has no greater distress in his perambulations of the streets than the average observant layman, only he pities those whom the layman does not observe, and sees no great hardship in the plights that must appeal to the uninitiated.

---

[1] Brit. Med. Jour., December, 1903.

In the last of the pathological groups to which we shall refer the medical man's knowledge is really useful. For we must all know the picture of the chronic invalid and cripple who year by year drags his deformed limbs before the pitying eyes (and purses) of his fellow-citizens and it is not difficult to imagine the feelings that are harrowed by so sorry a sight. As often as not, too, these victims wear an expression of the profoundest suffering which may impose upon many but cannot often deceive the trained eye. To the medical man it is perfectly evident that these ankylosed joints can have caused no pain for years. He recognises some old tuberculous trouble, arrested long ago, and never likely to recur unless the misguided patient shall submit to a so-called cure at the hands of a bone-setter, who will break down the adhesions and light up the old trouble afresh at the expense of an apparently straightened limb. The medical man, again, can tell very quickly that these congenitally dislocated hips are no warrant at all for the anguished look of their possessor whose abilities for the enjoyment of life are probably as great as those of most of his commiserators. Such cases as these, and they are too common upon our streets, cause the medical man to smile rather than to sigh and here his education will spare him many of the pangs that assault the softer-hearted of his comrades. And so the streets stretch out before him an infinite field for research and wonder and filled with all manner of substance for meditation. And with it all it is well to remember the exuberant sea of vitality that must abundantly overwhelm the pathological, even in the streets of London. And, doing so, the medical man of to-day will hesitate perhaps to subscribe to the opinion of old Sir THOMAS BROWNE in his "Religio Medici," that the world is "not an inn, but an hospital; and a place not to live, but to die in."

KING'S COLLEGE HOSPITAL.—The executors and trustees of the late Miss Marianne Frances Hasker have promised a donation of £20,000 towards the fund for the removal of King's College Hospital to South London.

Annotations.

"Ne quid nimis."

THE BIRTHDAY HONOURS.

Professor T. McCall Anderson, Mr. T. F. Chavasse, Dr. P. S. Jones, Dr. W. J. Smyly, and Dr. E. S. Stevenson have each had conferred upon them the honour of knighthood. Professor Thomas McCall Anderson, who is Regius professor of medicine at the University of Glasgow and the representative of his *alma mater* on the General Medical Council, graduated M.D. of Glasgow with honours in 1858 and obtained the Fellowship of the Faculty of Physicians and Surgeons of Glasgow in the same year. As the dean of the Medical Faculty of the University of Glasgow and as examiner in medicine and pathology to the Army Medical Service and the Indian Medical Service he has done good work in the interest of his profession and is the author of several books on cutaneous diseases and tuberculosis. Mr. Thomas Frederick Chavasse, the senior surgeon of the Birmingham General Hospital, is a justice of the peace for the county of Warwick. He graduated M.D. of Edinburgh in 1878 and obtained the Fellowship of the Royal College of Surgeons of that city in the same year and was made a Fellow of the Royal College of Surgeons of England, *honoris causâ*, in 1899. He is the author of various surgical monographs and has been a frequent contributor to the medical press. Dr. William Josiah Smyly, President of the Royal College of Physicians of Ireland, graduated M.D. of Trinity College, Dublin, in 1875, and became a Fellow of the College of which he is now President in 1884, having obtained the Fellowship of the Royal College of Surgeons in Ireland in 1877. He is a contributor to Allbutt and Playfair's System of Gynæcology and Quain's Dictionary of Medicine. Dr. Philip Sydney Jones, M.D. Lond., F.R.C.S. Eng., is honorary consulting physician to Prince Alfred Hospital and to Sydney Hospital, Australia, and Dr. Edmond Sinclair Stevenson, M.D. Brux., F.R.C.S. Edin., is a member of the medical council of the Colony of the Cape of Good Hope. The military branch of the medical profession is represented by Surgeon-General Charles McDonagh Cuffe, C.B., who has been promoted to Knight Commander of the Bath; Surgeon-Major Thomas Egerton Hale, V.C., a survivor of the Crimean War, and Surgeon-General William Launcelot Gubbins, M.V.O., Principal Medical Officer of the Western Command, in India, who have been made Companions of the Bath; and Colonel David Bruce, F.R.S., R.A.M.C., and Lieutenant-Colonel and Hon. Colonel William Coates, R.A.M.C. Volunteers, who also received similar honours in the civil division. To each of these gentlemen we offer in the name of the medical profession hearty congratulations.

PROPOSED CHARTER FOR THE BRITISH MEDICAL ASSOCIATION.

THE annual representative meeting in Oxford last year instructed the council of the British Medical Association to take the steps necessary to obtain the alterations in the memorandum of association contained in the Birmingham resolutions, subject to such modifications as might be required to harmonise them with the present articles. One of the Birmingham resolutions would have given power to the Association to expend money for the defence, promotion, or maintenance of the honour or interests of the medical profession, including in particular taking or defending legal proceedings. The matter was referred by the council to a committee, which has held numerous sittings and has taken legal opinions upon the course which should be followed. As a result the committee, at a meeting on June 2nd, requested the chairman of council to ascertain what prospect there would be of the Privy Council advising the Crown to grant a charter to the Association. Mr. Andrew Clark was able to report to a meeting of the committee on June 19th that as the result of inquiries at the Privy Council Office he had gathered the impression that the Association had a good prospect of obtaining a Royal Charter. The committee presented a report embodying the above facts to the council at its meeting on July 5th and the council then determined to report to the representative meeting that the information obtained as a result of inquiries as to the probability of the Association being granted a Royal Charter was so encouraging that it recommends the meeting to make an application to the Privy Council praying His Majesty to grant a Royal Charter.

VITAL STATISTICS OF THE JEWS.

THE desire has from time to time been expressed for trustworthy vital statistics of the Jews, partly perhaps on account of the absence in this country of any satisfactory basis for their calculation. No religious census has ever been taken in the United Kingdom; neither does the birth- or death-rate afford any information as to the religious persuasion of deceased persons or of the parents of children born. These facts, however, do not detract from, but rather add to, the interest of a paper read before the Royal Statistical Society on June 27th, entitled "A Contribution to the Study of the Vital and other Statistics of the Jews in the United Kingdom," by Mr. S. Rosenbaum. While it is difficult to accept as entirely satisfactory all the conclusions arrived at by the writer of the paper, based upon a number of somewhat hypothetical assumptions and estimates, he has brought to his task a sound knowledge of statistical method and of the fallacies that beset so much statistical work. The paper, therefore, deserves the careful attention of those who are interested in the subject. The total Jewish population of the United Kingdom is estimated at about 240,000, as the mean of two methods of estimation, based upon the recorded numbers of marriages solemnised in accordance with the usages of the Jews. Bearing in mind that a considerable, but unknown, proportion of Jews are admittedly married according to the rites of the Established Church, or are married in Nonconformist registered buildings or by a superintendent registrar without religious service, this estimation of the Jewish population in the United Kingdom is probably below the true number. Such under-estimate, however, would not affect some of the other conclusions arrived at by Mr. Rosenbaum. It appears from statistics relating to burials in Jewish cemeteries that an abnormally large proportion of young children are therein buried, from which was falsely assumed, by at least one witness at the recent Royal Commission on Alien Immigration, an abnormally high rate of infant mortality among the Jews. In the paper under notice the fallacy of such an assumption is clearly proved, as correct rates of infant or child mortality cannot be deduced from the recorded age at death without knowledge of the number of infants and young children born or living, which information is not available concerning Jews. Mr. Rosenbaum appears to establish the correctness of his assertion, with special reference to the aggregation of foreign Jews in the metropolitan borough of Stepney, that the birth-rate among this Jewish population is considerably higher than among the resident English population and that infant mortality is considerably lower, thus corroborating the general impression that Jewish women are remarkably good mothers. It appears that in the three quinquennial periods ending respectively in 1890, 1895, and 1900, while the metropolitan rate of infant mortality (deaths under one year to 1000 births) successively increased from 153 to 156 and 161, the rate in the borough of Stepney declined from 170 to 168 and 165. These figures do not show a low rate of infant mortality in Stepney, but they prove that the steady and remarkable recent aggregation of Jewish aliens in that borough has been accompanied by a decline of infant mortality concurrently with a general increase in the mortality of infants in the whole of the metropolitan area. The paper shows sound reason for believing that the Jewish birth-rate, at any rate in East London, is considerably higher than the non-Jewish birth-rate and that it was equal to 45 per 1000 in 1903. It is further asserted that this high birth-rate is not only due to the large proportion of Jewish women who are married but also to the greater fertility of Jewish wives. Whether Mr. Rosenbaum was well advised to use his hypothetical figures for the construction of a life table is open to some doubt, but the resulting table shows a higher expectation of life at all ages and for both sexes than is shown by life tables based upon the mortality of the general population of England and Wales. This is attributed not only to the more careful treatment of infants and children by Jewish mothers but also to the generally temperate habits of the Jewish population. The combined result of the high birth-rate and the low death-rate among the Jews is an abnormally high rate of natural increase, by excess of births over deaths. Mr. Rosenbaum admits that his conclusions have been mainly based upon the Jewish population of East London, which has an extremely abnormal age constitution, due to the alien immigration, including very few children or elderly persons, and it seems open to doubt whether the effect of this exceptional age constitution has been fully allowed for in estimating the marriage-, birth-, and death-rates of the population. The paper is, however, full of interest and many of the conclusions appear to be, in the main, well founded.

A CASE OF ABSCESS OF THE SPLEEN AFTER TYPHOID FEVER.

ABSCESS of the spleen after typhoid fever is a very rare complication and very few cases are on record. A case of exceptional interest is recorded by Dr. Federmann of Berlin in the *Deutsche Medicinische Wochenschrift*, No. 15, 1905, in which this condition occurred and was cured by operation. The patient was a labourer, 23 years of age, who was admitted into the Moabit Hospital for an attack of typhoid fever of moderate severity. On the eleventh day after the decline of the fever the patient developed a further febrile attack with leucocytosis. An exploratory puncture showed the presence of turbid purulent fluid in the left pleural cavity. About six centimetres of the ninth rib were removed subperiosteally and 300 cubic centimetres of this purulent fluid were evacuated; the lower lobe of the lung was adherent to the diaphragm which bulged upwards to a considerable degree. Subphrenic suppuration was in consequence suspected and on puncture thick brownish pus escaped. On incision below the diaphragm 500 cubic centimetres of stinking pus, containing masses of necrotic spleen tissue, were discharged, leaving a space, as large as two fists, with very thin walls, beyond which the stomach, the liver, and coils of gut could be distinctly felt. The abscess occupied practically the whole of the upper half of the spleen. The cavity was carefully cleaned out and packed with iodoform gauze. Convalescence was somewhat protracted but three and a half months later the patient left the hospital, his wounds being completely healed. Since that time he has remained healthy and is able to work. Dr. Federmann, in discussing the diagnosis of the condition, considers that the important features of the case were the evidence of fluid in the pleura and the leucocytosis. As is well known, uncomplicated typhoid fever produces a state of leucopenia or a reduction in the number of leucocytes. In this case a leucocytosis of 14,000 per cubic millimetre occurred in the second week of the illness, subsequently increasing to 25,000. The surgical treatment of the condition offers a very fair chance of recovery, since in the 27 cases recorded in the literature there is only a mortality of 15 per cent.

TEA AND THE EFFECTS OF TEA-DRINKING.

WHILE everyone knows that it is wrong to stew tea, to draw from it as much of its astringent principles as possible, yet there are few who pay any practical regard to the warning not to prepare tea in this way. It cannot be too widely known that not only is theine the most essential constituent of tea but also that it is almost as quickly soluble in hot water as is sugar. The making of the infusion is therefore complete in a few minutes and only tea so prepared is the "blessed beverage." The abuse of tea, like the abuse of anything else, is, of course, reprehensible and the guilty person deserves all the unpleasant symptoms which excessive tea-drinking or the drinking of strong, stewed tea sooner or later brings in its train. The subject is a well-worn one but in view of the enormously increasing consumption of tea in this country it is desirable to return to it and to remind our readers to impress upon their patients the undoubted evils to which immoderate and careless tea-drinking gives rise. In 1893 THE LANCET Analytical Commission published a report on "Tannin and Theine in China and Indian Teas" which was based on a number of laboratory experiments and the results were distinctly instructive, leaving no doubt as to the way in which tea should be consumed if the vicious principles are to be eliminated and the virtuous principles retained. More recently Dr. W. Scott Tebb, public analyst to the metropolitan borough of Southwark, has conducted an investigation at the instance of the Southwark borough council on similar lines and his report printed in pamphlet form contains some interesting observations on the subject of Tea and the Effects of Tea-Drinking. He concludes, and we are inclined to agree with him, that in the first place we drink too much tea as shown by a simple calculation from the average annual amount imported for consumption. Then as regards the best method of preparing tea, he recommends that the tea should be infused (not stewed or decocted) for no longer a period than five minutes. As to the variety of tea, he says that although it is not certain that the average China teas contain less tannin than do the Indian teas there is no doubt that individual samples of China tea can be procured comparatively free from this astringent principle. Tea, he suggests, should be examined for the amount of alkaloid and tannin and the price should be based on the proportion of the essential ingredient, the alkaloid; and the public should in each case, he thinks, be informed of the quantity of tea required to be used with boiling water—according, in fact, to the alkaloidal contents—and at the same time an indication should be given of the proportion of tannin liable to be extracted in a standard infusion. Such a procedure, surely, would be utterly impracticable and we doubt if it is scientifically sound. To begin with, the quality of tea bears no sort of relation to its alkaloidal contents any more than does the quality of tobacco depend upon its proportion of nicotine. The best cigar or tobacco does not necessarily contain the smallest amount of nicotine. Again, the proportion of tannin extracted depends upon the kind of water used. As was shown in the report of THE LANCET Commission referred to, soft or distilled water (which latter, by the way, Dr. Tebb employed in his experiments) dissolves the tannin more rapidly than does tap water but effects no increase in the amount of theine dissolved. Hard water will, indeed, render part of the tannin insoluble. Much depends, too, on the size of the leaf and there is no doubt that the most economical way of preparing tea is to powder it, in which case the time during which it is allowed to infuse can be considerably shortened, although the alkaloid and flavouring substances will be almost completely extracted. Another point to which we may draw attention is that caffeine and tannin are chemically antagonistic; they may also be to an extent physiologically antagonistic also. A hot infusion of Indian tea when allowed to cool yields a considerable deposit containing both tannin and theine. Tannin, in truth, is a precipitant of many alkaloids and a strong solution either of tannin or of tea is directed to be administered in certain cases of poisoning by alkaloids. It is probable that the physiological action of an infusion of tea is not identical in every respect with that of pure theine. The tannins comp an exceedingly numerous class of substances the memb of which do not behave physiologically or chemica in the same way. Tannin is present, for example, tea, in coffee, and even in cocoa, but the astringent p perties of the three beverages are very different, thoug the actual amount of tannin consumed may be t same. The use of plenty of milk with tea, it may be adde is a wise precaution and must be regarded as a soun physiological proceeding, since the proteids of milk destro astringency and probably prevent the otherwise injurio action of tannin on the mucous membrane of the stomach. In the intestinal juice the proteids are separated and the tannin probably combines with the sodium salts. The immoderate drinking of tea is an unquestionable evil but, on the whole, we are inclined to think that the evils of tea-drinking have been exaggerated. The real difficulty is to convince people that a lightly drawn infusion gives them their money's worth.

THE BLOOD PRESSURE IN CONVALESCENTS: "THE HYPOTENSION OF EFFORT."

AT the meeting of the Société Médicale des Hôpitaux of Paris on May 5th M. C. Oddo described an interesting phenomenon which he had observed in studying the blood pressure of convalescents—a fall of pressure after slight effort, such as going rapidly round the ward or ascending and descending two flights of stairs. This he terms the "hypotension of effort." Usually there was produced first a brief and feeble rise of pressure; after a minute the fall began and lasted for two or three minutes; five minutes the pressure became again normal or rem for some time below the normal and regained the n slowly. In other cases there was no rise of pressure an fall immediately followed the effort. The fall of pre usually amounted to from one to two centimetre mercury on the sphygmomanometer of Potain, but somet it amounted to as much as four centimetres. Us the blood pressure was subnormal before the experim varying from 11 to 14 centimetres of mercury, but s times the pressure was normal; in several cases a pres of 16 or 17 centimetres fell after the effort to 13 or This fact is of particular interest because it shows tha convalescents the blood pressure is not only feeble unstable, and that it may be unstable without being fee The frequency of the pulse generally follows the bl pressure—that is to say, the pulse is momentarily accelera after the effort, then rapidly falls, and finally beco normal at the same time as the blood pressure. T is in contradiction to Marey's law but exceptio to it in disease are well known. However, in so cases the pulse rate increases while the tension fal e hypotension of effort is not constant in con- lescence; it is most frequent in the early stages hen the blood pressure is low but even then it may absent. In the normal state the effect of effort is to crease the blood pressure. But when exertion is carried to e point of fatigue the pressure falls. It is easy to under- and why a slight effort has the same effect on the blood ressure in convalescence as prolonged exercise or violent fort in health. Exertion during convalescence submits the eart to a task which is too great; it is unable to discharge nto the arteries sufficient blood to maintain and to elevate he pressure. If cardiac fatigue immediately follows the effort ypotension results. But if the heart preserves enough of nergy to discharge into the arteries the excess of blood rought to it by the veins the blood pressure is momentarily aised. Then the increased work is followed by exhaustion nd the blood pressure falls. The vessels also play a part: heir muscular fibres are exposed during the effort to an in- reased strain; they become exhausted and relax, contributing o the fall of pressure. Usually these two factors, cardiac nd vascular, combine in producing the hypotension. But ometimes the predominance of one or the other is observed linically. The cardiac factor is shown by tachycardia, rhythmia, and feebleness of the sounds; the vascular y vaso-dilatation of the lower part of the body in the tanding posture, redness or pallor of the face, and ermographia. The last M. Oddo has often observed in convalescents. It follows that to appreciate the cardio-vascular condition of convalescents it is not sufficient to measure the blood pressure during rest but also to ascertain its stability after exercise.

THE CHOICE OF AN OCCUPATION FOR THOSE WHO SUFFER FROM AFFECTIONS OF THE EYES.

SYSTEMATIC examination of the eyes of school children seldom fails to show that a considerable proportion of them have defective sight and will therefore be placed at a disadvantage if in after life they engage in employments for which normal vision is desirable. Some useful suggestions on the practical side of this question will be found in Dr. Wilhelm Feilchenfeld's "Gesundheitspflege des Auges." He says, for instance, that sufferers from sensitive eyes, with easily irritated conjunctiva, or with chronic or frequently occurring inflammation of the lids, ought not to engage in work which is either associated with the production of much dust—such as baking or milling—or which involves exposure to a dazzling light, such as the occupation of a furnaceman. Individuals in whom symptoms of ocular fatigue easily come on ought not to choose an occupation which requires straining of the eyes by long-continued near work, such as sewing, knitting, copying, or shorthand writing. Individuals with one eye only should be warned against all kinds of employment which frequently lead to injuries of the eyes, such as metal-working or stone-masonry, because to such persons any injury to the eye is exceptionally serious. Also, one-eyed individuals should not choose any occupation which demands a very exact estimation of distance, because for this vision with both eyes is almost absolutely necessary, although a person can learn, up to a certain degree, to estimate distances with one eye alone. Individuals with progressive shortsightedness must avoid all occupations which entail great exertion upon the eyes; they should not engage in study, or become clerks, or mechanics, tailors, dressmakers, fancy needleworkers, or quilters; on the contrary, agriculture, gardening, milling, or brewing should be recommended to them, or they could become shop assistants, or, if women, cooks. Individuals who are colour-blind should not become seamen, and, if employed on a railway, it should not be in the outdoor department. Individuals who require to wear spectacles always, on account of some error of refraction, ought not to be employed near a furnace or in rooms containing steam, because in such places the spectacles continually become steamy and so cause indistinct vision; such individuals, therefore, are not suitable, e g., for locksmiths, engine-drivers, firemen, or, if women, for laundresses.

FOURTH-OF-JULY TETANUS.

EXUBERANT patriotism is not without attendant dangers. In any case the health authorities of Chicago have issued a timely and official warning. The bulletin of the health department, published a fortnight before the event, discusses the proper treatment of Fourth-of-July wounds. The American Medical Association and its journal have often dealt with the question of the "prophylaxis of the Fourth-of-July tetanus." The celebration of American independence, when loyal citizens endeavour "to blow the country off the map," produces what is described as thousands of "useless injuries." These are caused very generally by premature explosions of blank cartridges and are frequently followed by tetanus. It is therefore urged that large quantities of tetanus antitoxin should be held ready at the disposal of the public on every July 4th. According to the available information no case of lockjaw has occurred when this preventive has been used. It is also considered perfectly harmless. Consequently it was employed in a large number of hospitals last year and efforts have been made to insure its wider use on the present occasion. The only deaths from tetanus were among those who had not used the antitoxin before the symptoms of the disease had appeared. It is odd that national rejoicings should lead to numerous and fatal injuries. Nothing could be more brilliant than the fêtes of July 14th in France and they do not occasion such accidents. But the French people generally trust "the Administration" to manage matters for them and leave pyrotechnic displays in the hands of specialists fully qualified to handle these explosives. If in America the money which each individual spends in squibs and petards was paid into a central fund a display of fireworks really worth seeing could be organised, and this without endangering the lives of the citizens.

THE ANATOMICAL AND FUNCTIONAL INDEPENDENCE OF THE LOBES OF THE LIVER.

M. H. Sérégé has contributed an interesting paper to the Académie des Sciences of Paris[1] wherein he argues that the lobes of the liver are anatomically and functionally independent, advancing anatomical, physiological, pathological, and clinical reasons in support of his views. The anatomical independence of the lobes was affirmed by Glenard in 1895 and confirmed by Wertheimer and Lepage in 1896. The writer considers the proposition is proved by the injection of a solution of methylene blue into one of the branches of the portal vein when it is observed that only one lobe is coloured by the dye. The physiological independence of the lobes is demonstrated by the existence of a double current of blood in the portal vein. If a drop of Chinese ink be injected into a small vein of the small intestine the coloured particles are found in the right lobe, but if the ink be injected into the splenic vein the particles reappear in the left lobe. Another physiological proof consists in the determination of the amount of urea present in the different lobes. It has been observed that the left lobe contains the most urea until the third hour of digestion, after which the right lobe contains the most until the next meal is taken. During abstinence from food both lobes contain an equal quantity of urea. Again, the determination of the quantity of glycogen present in each lobe during digestion shows that the left lobe is richest in glycogen until the third or fourth hour of digestion and the right lobe contains the most from the fourth to the tenth hour. But if the fasting be prolonged it is surprising to note that from the twelfth hour onwards and until the next meal the left lobe again contains the most glycogen. In conjunction with Dr. E. Soule, M. Sérégé determined the rate of flow of blood in the right and left lobes. The flow was more rapid in the right lobe than in the left, a result which is in agreement with the work of M. Jolyet and M. Rosapelli, and offers a rational explanation of the difference in the quantity of glycogen present in each lobe. M. Sérégé further considers that the records of pathological anatomy and clinical experience in medical literature furnish ample evidence of the independence of the lobes of the liver.

A DEAN'S OPINION AS TO CLEANLINESS.

THE Dean of Canterbury appears to hold views which, we hope, are peculiar to himself upon the virtue proverbially described as holding a position next to godliness. He is reported as having delivered himself recently of sundry observations upon the subject of luxury among modern schoolboys at the celebration of the jubilee of the Clergy Orphan Corporation at St. Edmund's School, Canterbury, and to have held up to his audience as an example of the sybaritic tendencies of the age the fact that the governors of a great public school "had actually found it necessary to provide the poor little boys with shower baths when they came in from football." He appears to have added, by way of explaining his point of view, that when he himself was a schoolboy "there was scarcely anything necessary for the purpose of his education except a room, a book, a man, and sometimes a stick." Making every allowance for the humorous side of this description it would seem that the Dean of Canterbury considers that the modern mechanical aids to cleanliness are not desirable so far as boys are concerned because when he himself was a boy he was not provided with them. The word "necessary" is a somewhat misleading one. Cleanliness is an adjunct and aid to healthy life but no sanitary precaution is "necessary" unless we start by regarding it as "necessary" to provide for the young the healthiest surroundings that are reasonably attainable and to train them to the use of sanitary appliances for their own benefit. Schoolboys are never likely to carry washing to excess, but they come from a game of football on a moist November day begrimed with mud, their clothes damp with perspiration, and sufficiently fatigued to be grateful for the refreshment of a bath. Clean and dressed again in dry clothing they are more likely to benefit by the healthy exercise which they have taken than if they remained dirty and in their wet clothes and we ask the Dean of Canterbury whether he would seriously deny this. Perhaps he would answer that they should be allowed to change their clothes if these are wet and muddy, although no doubt in the days when he was young change of clothes for games was less universal than now. Would he, however, suggest that a boy should change his clothes when they are dirty but should not cleanse his skin when it is in a similar condition? And if the boy is to wash is there any reason why he should not be furnished with a form of bath which will insure his doing it efficiently and rapidly without giving him the opportunity for soaking himself in warm water, a performance which might fitly be described as a luxury and as one likely to lead to undesirable results? If the Dean of Canterbury does not agree with us let him visit a room full of boys fresh from football in the act of changing their clothes and of performing such ablutions as may be within their reach and he may not only modify his views as to the "necessity" of shower baths and as to their position as luxuries, but may also feel that as a schoolmaster he would prefer to be shut up on a winter's afternoon, with a class of lads fresh from their luxurious baths to instructing the same youths in the hardier circumstances which he recalls as characteristics of his own boyhood. It is not a little disappointing to those who have at heart the education of all classes of the nation to the appreciation of healthy conditions of life to find an eminent member of the ecclesiastical profession belittling cleanliness as a superfluity and a luxury The clergy occupy an admirable position for the teaching of many things besides the doctrines and precepts of religion and they are not as a rule averse from interfering in purely medical matters or from lecturing upon subjects which have no direct connexion with their vocation. It would neither compromise their dignity nor diminish their usefulness if they were to put themselves in the forefront of the sanitary progress of the present day, but it cannot be said that they have hitherto done so to any marked extent. Schools in which they have held considerable, if not paramount, authority have not always been conspicuous for the high quality of their sanitation. Ventilation in churches is by no means carried to the point of making them wholesome places for large numbers of persons to remain in for an hour or two at a time The Dean of Canterbury, however, seems to have gone further than mere indifference to undesirable conditions which others view with disapproval and to have suggested that cleanliness must be obtained with difficulty or must be deemed a luxury, and to have been influenced in doing so by the fact that it was not regarded as worthy of consideration when he himself was young. Those who remember public schools in those days, however, and who are acquainted with the schoolboy of the present century sufficiently to know what his life really is and to compare it with their own, will probably think that if his existence is more luxurious than it would have been in the last generation it is cleaner, happier, and better, not only physically but morally. It is the effort, at all events, of those who supervise it to make it so and they will probably not relax their efforts because the improvement which they seek to introduce was not 50 years ago regarded as "necessary."

SECONDARY FACTORS IN THE MORTALITY AND TRANSMISSIBILITY OF PULMONARY TUBERCULOSIS.

AT the first medical congress of the Republic of Cuba, which was held in Havana on May 23rd, Dr. Carlos J. Finlay, chief sanitary officer of the Republic, read a preliminary note on the Importance of certain Secondary Factors in the Mortality and Transmissibility of Pulmonary Tuberculosis. THE LANCET of May 27th contained a report of a paper on the Significance of Phthisis Death-rates, read by Dr. Arthur Ransome before the Epidemiological Society in London on May 19th, and when that issue of THE LANCET arrived in Havana on June 9th Dr. Finlay was kind enough to send us an abstract of his paper. He holds it to be an aphorism that the tubercle bacillus *in pure culture* is practically incapable of developing in the pulmonary tissues either the anatomical or the clinical symptoms characteristic of confirmed pulmonary tuberculosis, and he considers that precautions against the infection of healthy persons by bacilli from the sick are not nearly so important as the elimination, both for the sick and the healthy, of everything that may tend to paralyse in the human organism the natural resources with which it is endowed for its defence against the invasion and development of the tuberculosis infection. He says that the two resources which the human system possesses against the aggressions of Koch's bacillus are. first, the phagocytic properties to he leucocytes and, secondly, the stimulus towards proferation experienced by the connective tissue cells nder the action of the secretions of the bacillus. nder the influence of this stimulus the connective tissue ells build up around the bacilli a capsule which on the one and protects the bacilli against the avidity of the phagoytes and on the other impedes the multiplication of the acilli as well as the transudation of their secretions towards he adjacent tissues. The protection obtained by the atient through the encapsulation of the bacillary focus is iable, however, to be precarious, inasmuch as if in its eighbourhood a focus of pyogenic bacteria should be nstalled these through their necrotic and ulcerative endencies may destroy the walls of the protective apsule. Such bacilli as may have survived will thus e set free; they will multiply and with the proection that their association with the pyogenic bacteria ill afford them against the phagocytes, they will ccomplish the work of destruction in the adjacent tissues nd will bring about the formation of new foci either within he body of the same patient or externally wherever particles f the mixed culture (tuberculo-pyogenic) may have been onveyed from their original site. Among these pyogenic acteria Dr. Finlay includes not only the staphylococcus and treptococcus but also Friedländer's and Frankel's cocci, he bacillus of influenza, and the micrococcus tetragenus of affky, and he naturally arrives at the conclusion that the est prophylactic of tuberculosis and the best remedial reatment are the *respiration of pure air.*

STANDARDS AND THE SEASONAL VARIATION IN THE COMPOSITION OF MILK.

THE adoption of analytical standards in regard to milk whilst affording a certain degree of protection to the community against adulteration is not calculated to secure the supply of milk of maximum quality. It is evident that the temptation to water a rich milk or to reduce the fat to such an extent that it still complies with the requirements of the standard is, in many instances, irresistible. In the recently published report, for example, of the public analyst of the borough of Portsmouth, Mr. Edward Russell, B.Sc., F.I.C., for the year ending Dec. 31st, 1904, the figures indicate a studied and systematic sophistication of the milk-supply of that borough. The figures, that is to say, run perilously near the legal limit, or, in some instances, are just that trifle below which makes it difficult to differentiate between a poor genuine sample (in the light of the legal minimum) and a tampered milk. When the analyst calculates that the milk is adulterated with 5 per cent. of water or is deficient in fat to the extent of 5 per cent., based on the legal standard, the extreme probability is that the milk has been tampered with to a larger extent than these figures would indicate. As suggested by Mr. Russell, it would be well if the calculation of the extent of the adulteration in those cases in which the fat falls below the minimum legal limit could be based on such a standard as the mean between the two lowest points of the curve given in a table showing the seasonal variations of genuine milk. The curve of undoubtedly genuine samples is practically parallel in this table with the curve illustrating the variation in the general supply. As an example a milk showing 2·85 per cent. of fat on analysis is quoted. This would be reported as being deficient in fat to the extent of 5 per cent. below the legal minimum, whereas if the standard figure 3·4 (the lowest point of the general curve) were used as the basis of calculation the deficiency would be represented as 16 per cent., which is probably much nearer the truth. As is well known, distinct variations occur in the quality of milk at periods in the year corresponding with the seasons. Thus in winter milk is of good quality, while in summer the milk is poorest, and in the spring and autumn the quality is neither rich nor poor. The plan suggested seems to us to be worthy of attention and its adoption would undoubtedly result in a considerable improvement in the quality of the milk-supply.

PATHOLOGICAL MATERIAL SENT BY POST.

THE attention of the Postmaster-General has been drawn to the fact that pathological specimens are frequently sent by post by members of the medical profession and other persons in packets which have not been registered as required by the Post Office regulations. The Postmaster-General desires to give notice that the transmission of such specimens is sanctioned only on the condition that they are handed in at a post office for transmission by registered letter post, and that they are packed in accordance with the regulations published in the Post Office Guide. These regulations, which are necessary for the protection of Post Office servants and of the public, provide that any deleterious liquid or substance sent by post must be inclosed in a receptacle hermetically sealed, which receptacle must itself be placed in a strong wooden, leathern, or metal case in such a way that it cannot shift about, and with a sufficient quantity of some absorbent material (such as sawdust or cotton-wool) so packed about the receptacle as absolutely to prevent any possible leakage from the packet in the event of damage to the receptacle. The packet must also be marked "Fragile, with care." Any person who sends by post a deleterious liquid or substance for medical examination or analysis otherwise than as provided by these regulations is liable to prosecution, even if he be a patient sending something to his medical adviser for his opinion or a medical practitioner sending something to a laboratory or elsewhere.

THE DANYSZ VIRUS FOR FIELD PESTS.

AN example of the national character of the work undertaken by the Pasteur Institute in Paris is afforded by the annual report of the British Consul at Bordeaux, just published. In the department of Charentes, which lies to the north of Gironde, the crops have suffered terribly from the inroads made by a small animal described as something between a field mouse and a field rat. These rodents, as a rule, occupy the lower marshy ground, chiefly meadows and pasturage; but the floods following the heavy rains of 1902–03 drove them from their natural habitat on to the higher arable land, where they wrought serious havoc. In spite of various efforts at extermination they throve in their new quarters and multiplied at a terrific rate, their numbers being estimated at from 1,000,000,000 to 1,200,000,000. Nux vomica was the chief medium employed to rid the country of these marauders but it proved unsatisfactory inasmuch as small birds, game, domestic fowls, and animals were freely numbered among its victims. Then the Pasteur Institute came to the rescue with a specially prepared remedy. At first this Danysz virus did not prove very efficacious until experience taught that it must be distributed while fresh and protected, as far as possible, from the action of light. The practice adopted was to prepare the rolled oat grain used as bait in dimly lighted sheds and to spread it on the fields in the evenings. Under these conditions it is claimed, says Mr. Vice-Consul Hamilton, that "the mortality induced by it in the field mice, as the result of recent experiments, is as high as 98 per cent. within 15 days, as not only those 'campagnols' which have eaten the bait die within five days but the others are infected by the disease and die in their turn. The contagious malady induced by the Danysz virus resembles typhoid but is innocuous to all living beings except rats and mice, to which animals it is fatal. There is a special service attached to the Pasteur Institute in Paris for the preparation of this virus, which is prepared in combination with a tempting broth and is sent down to the Charentes in bottles on receipt of requisitions from the mayors of the communes affected. The inhabitants of many communes are marshalled by the mayor in semi-military formation and the bait spread methodically in such a manner as to leave no portion of ground without its share of poisoned grain."

LECTURES ON EXPERIMENTAL PSYCHOLOGY.

WE have received a prospectus announcing the following courses of lectures in experimental psychology at King's College, London, for the ensuing academic year. In the first term Professor W. D. Halliburton will lecture on the General Structure and Histology of the Nervous System and of the Sense Organs. In the second term a course of eight weekly lectures will be given by Dr. C. S. Myers on Modern Investigations in the Psychology of Memory. Dr. Myers will also deliver during the second and third terms a course of lectures in Experimental Psychology, accompanied by demonstrations and laboratory work in the rooms of the new psychological laboratory which adjoin the physiological laboratory of the college. The second term's work will be mainly devoted to the study of sensations and their relation to experiences of space, form, weight, time, rhythm, and harmony; the third term mainly to the study of attention, fatigue, practice, work and memory, the effect of drugs, the chronometry of mental processes, and the general principles of psycho-physical research. For the benefit of students of the laboratory a departmental library has been started which contains the principal English and foreign books and periodicals devoted to general and experimental psychology. The days and hours of the lectures are not yet fixed but would-be students are requested to communicate with the Secretary of King's College.

THE MODE OF ORIGIN OF NEOPLASMS.

AT the meeting of the French Academy of Science held on May 29th there were presented two papers bearing upon the question of the development of malignant growths. In one of them, entitled "Reproduction Expérimentale du Cancer de l'Homme," M. Mayet claimed to have succeeded in infecting a dog by means of fluid obtained by the maceration of the tissue of a uterine myoma. On May 4th and May 14th, 1904, there were injected into the animal respectively 20 cubic centimetres and 40 cubic centimetres of the fluid, after this had been filtered through porcelain and the absence of perceptible organisms had been confirmed by the use of the microscope. The dog died on May 18th, 1905, and there was then found in its spleen a tumour which was described as being of the size of a nut and of sarcomatous character. This experiment M. Mayet regarded as supporting his earlier observation that tumour juice would set up in white rats processes giving rise to the production of neoplasms differing in form from that of the original tumour and situated far from the region of injection. The second paper referred to was by M. Charrin and M. Le Play and dealt with the effects produced by the subcutaneous and intraperitoneal injection of pure cultures of the fungus stearophora radicicola which grows upon the root of the vine. Under the skin and mucous membranes of the animals examined were found nodules made up of lymphocytes, polynuclear leucocytes, and a few connective tissue fibrils, together with a network of the mycelial filaments of the fungus. The growths attained in some cases the size of a pigeon's egg and contained a good deal of black pigment, giving them a melanotic character. In the liver and kidneys there were further growths, different in the two organs. Hæmorrhagic foci occurred in the spleen, the medulla of the suprarenals, and the nervous system, and there was diminution in the numbers of the red corpuscles and in the amount of hæmoglobin. Most remarkable, however, were the changes in the skeleton. The bones were found to be altered in composition, there being a diminution in the quantities of water, phosphoric acid, and lime normally present, while individual bones were deformed from the development in or upon them of curvatures and nodosities. Other parasites of the same group produced effects displaying a general similarity to those above mentioned. These researches may be correlated with those of Plimmer, whose experiments led him to the conclusion that the "cell inclusions" found in malignant growths are parasites allied to the saccharomycetes, for there is some reason to think that both saccharomyces and stearophora are degenerate members of the group of fungi known as ascomycetes.

THE BRITISH ELECTRO-THERAPEUTIC SOCIETY.

AS will be seen by a reference to our advertising columns, this society intends to hold its provincial meeting at Leicester on July 26th, 27th, and 28th, during the visit of the British Medical Association. These meetings will be free to all members of the British Medical Association and other qualified medical men. A programme of the papers to be read and discussions to be held will shortly be announced and any medical practitioner wishing to take part in the discussion or to read a paper is invited to communicate without delay with the honorary secretary, Dr. E. Reginald Morton, 22, Queen Anne-street, London, W. The British Electro-Therapeutic Society is doing good work in the application of electrical forms of energy for the cure and relief of disease and one of its most stringent rules is that its members must be qualified medical men.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE sixty-fourth annual meeting of this association will be held on July 20th and 21st at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Dr. T. Outterson Wood. The educational committee will meet on July 18th at 4 P.M. and the parliamentary committee on the 19th at 5 P.M. The adjourned annual meeting will be held on the 19th. On the 20th the council will meet at 9.30 A.M. and the annual meeting will commence at 11 A.M. With regard to the election of officers, council, and standing committees, we are asked to remind members that the voting papers must either be handed in at the annual meeting or sent by post to the general secretary at 11, Chandos-street, London, W., so as to reach him at least seven days before the date of the annual meeting and must be legibly marked on the outside "Voting Paper." There are eight candidates proposed for election as members. After the various elections have been decided, several reports received, and other formal business transacted the annual meeting will re-assemble at 2 P.M. when the retiring President, Dr. R. Percy Smith, will introduce his successor, who will present any prizes or medals that may have been awarded during the year. The President will then deliver his address. Immediately after the presidential address Dr. George M. Robertson, medical superintendent of the Stirling District Asylum at Larbert, will introduce for discussion the question of the Employment of Female Nurses for the Care of Insane Men and several members have promised to take part in the discussion. On the 21st, at 10 A.M. (in view of the introduction of two Lunacy Bills in Parliament), the question of the treatment of insanity and the proper accommodation to be provided, especially for early mental disorders, will be brought forward for discussion. Dr. Helen Boyle, late an assistant medical officer in the London County Asylum, Claybury, will read a paper upon Some Points in the Early Treatment of Mental and Nervous Cases, with Special Reference to the Poor. Dr. J. Milson Rhodes, member of the Lancashire asylums' committee and member of the committee which reported upon asylums in the United States, will read a paper upon the Provision of Suitable Accommodation for the Various Forms of Insanity. Dr. Alan McDougall will read a paper upon the David Lewis Colony for Epileptics, Alderley Edge, of which he is the resident medical officer. At 2 P.M. the question of pulmonary tuberculosis in asylums will be brought up for discussion. Dr. George W. Greene, medical officer, Claybury Asylum, will read Notes upon the Incidence of Tuberculosis in Asylums. The following papers are also promised: Some Definitions, by Dr. Charles A. Mercier, and Some Remarks in Regard to Urine Testing, by Dr. Robert Jones. The annual dinner will take place on July 20th at the Whitehall Rooms, Hôtel Metropole, London, at 7.30 P.M. Tickets one guinea (wines included).

INFORMATION has just come to hand that the committee of organisation of the Fifth International Congress of Obstetrics and Gynæcology, having received numerous intimations from gynæcologists in Russia and outside that country suggesting that the Congress should be postponed for a year, has decided, after a discussion at a special meeting, to put off the Congress, which was to have been held in September, 1905, in St. Petersburg, to next year (1906).

IN connexion with the visit to England of their Imperial Highnesses Prince and Princess Arisugawa of Japan the King has appointed Dr. Ishinoské Mimura, physician to His Imperial Highness Prince Arisugawa of Japan, to be an Honorary Member of the Fifth Class of the Royal Victorian Order.

THE distribution of medals and prizes to the students of Guy's Hospital will be held at the hospital on Wednesday, July 12th, at 3.15 P.M. The governors and the medical staff are giving a garden party on the occasion and the prizes are to be distributed by Dr. P. H. Pye-Smith, F.R.S.

INVITATIONS to a Conference on the Prevention of Epidemic Small-pox, to be held at the Mansion House, London, on Tuesday, July 18th, at 3 P.M., have been issued by the Lord Mayor.

Dr. G. E. Herman, consulting obstetric physician to the London Hospital, has been elected an honorary member of the Gynecological Society of Chicago.

THE Long Fox Memorial Lecture for this year will be delivered by Dr. E. Markham Skerritt in November.

EPSOM COLLEGE JUBILEE.

ON Saturday last the jubilee of the opening of Epsom College was celebrated by a large gathering of old boys at the College. Close upon 250 arrived between 3 and 4 P.M. and many of the older ones were greatly interested in talking over old times and in observing the improvements introduced since their days. A large number of the visitors found their way to the cricket field where they witnessed the close of a match between the College team and Merchant Taylors' School. Refreshments were served in the headmaster's garden at 4.30, there was a short service in the chapel at 5.45, and a party of considerably over 200 sat down to dinner in the big school-room at 6.30 under the chairmanship of Mr. Henry Morris, one of the earliest scholars, and at present honorary consulting surgeon to the College. He was supported by the Earl of Rosebery, President of the College, Sir Richard Douglas Powell, Sir Constantine Holman, Dr. F. Needham, Dr. F. de Havilland Hall, Dr. J. H. Galton, and Dr. M. Baines, and by the following amongst other prominent old boys, Mr. H. Robertson, M.P., Surgeon-General A. M. Branfoot, C.I.E., I.M.S., Dr. Frederick Taylor, honorary consulting physician to the school, Mr. Bilton Pollard, Mr. George C. Croft, and Mr. C. L. Smiles, chairman of the Jubilee Committee. Archdeacon Thornton, the first headmaster of the College, was too unwell to be present, but he sent an interesting letter of congratulation on the successes achieved and of the progress made, with his affectionate remembrances to his old friends.

In proposing the toast of "His Most Gracious Majesty the King, Patron of the College," the CHAIRMAN referred to the fact that His Majesty had visited the College as a lad of close upon 14 years of age when his father, the Prince Consort, opened the College in 1855, and that His Majesty laid the foundation stone of the lower school in 1895. Moreover, the present Prince of Wales was following in the footsteps of his father, for so recently as in 1903 His Royal Highness had visited the College and had taken the chair at a festival dinner. The toast having been drunk with enthusiasm, the Chairman proposed the toast of the evening, "Success to Epsom College." In a long speech, during which unfortunately many guests were compelled to leave the room in order to catch the last train from the Downs station, he sketched the growth and educational progress of the College. He observed that when the College was opened there were only about 18 acres of land and the buildings accommodated 150 scholars; but now the College possessed close upon 80 acres and was able to accommodate from 300 to 350 boys, including those in the lower school. He gave an interesting account of the introduction of lectures in chemistry and natural philosophy about ten years after the opening of the College and of more time being allowed a few years later for the study of modern languages at the expense of classical studies. About this time the council built a proper laboratory and made large additions to the apparatus, a class-room fitted up as a laboratory having served the purpose for some years, and a year or two later the study of botany, the elements of physiology, and zoology was started. He referred to the numerous improvements which had been introduced in recent years and drew attention to the fact that these were in a great measure due to the efforts of the treasurer, Sir Constantine Holman. He observed that the College was now recognised as a school of science by the English Conjoint Board of the Royal Colleges of Physicians and Surgeons. In conclusion, he referred to the fact recently mentioned in our columns that when granting her patronage to the College 50 years ago Queen Victoria expressed the wish that the designation of the institution should be "The Royal Medical College," thus omitting the objectionable word "Benevolent," which existed in the title until 1903, when it was altered to "Epsom College."

In responding to this toast Lord ROSEBERY spoke as follows: Mr. Chairman and Gentlemen,—I speak to you under singular disadvantages to-night, because I have by some blunder of my own undertaken to do that which no man, however great, has ever been able to do, which is to eat two dinners; and I have the uneasy consciousness that for the last 40 minutes a dinner party has been waiting for me at my house. That will conduce, at any rate, to the brevity of my speech; but I am afraid that there is another reason for that brevity even more efficacious—namely, that I cannot, though president, speak with that internal knowledge of its arrangement which alone would justify me in detaining you. I do, indeed, as a neighbour take a great pleasure in visiting the College and watching the matches at cricket and football in which the College is so eminently distinguished, but I take no part in the teaching; and I am inclined to think that if it was known that I did take part in the teaching not only would it have a serious effect on the views of the parents of Epsomians but it might seriously tend to reduce the standard of the teaching itself, so I must lead you into other branches of education which are not touched on here. Well, gentlemen, I can, at any rate, speak with some knowledge not on the process by which Epsomians are turned out but of the result, and I venture to say that no finer body of young sent out by Epsom College. It turns out Englishmen and English gentlemen, healthy in mind and in body, fit to go anywhere and to do anything, and it is my belief that if the number of schools like Epsom College were multiplied, and if the number of scholars inside Epsom College were multiplied, it would be none the worse for this country or this Empire. I am sometimes puzzled by one very curious anomaly. In this country we have the best raw material in the world. We turn out annually thousands of young fellows splendid in physique, energetic in mind, and not ill-trained intellectually as compared with other nations, the most valuable body that a nation can have. Now, in an Empire like ours there should be an unlimited demand for such men. There is practically an unlimited need for such men and yet why is it that the demand and supply in this country do not coincide? You never sit next to parents at dinner who know the least in the world what they are going to do with their sons. It is the great problem of the age. While this is certainly true, and I, as a parent, speak with the utmost sympathy of the difficulty of finding proper avenues of employment for one's sons, some find it in the cricket field, some elsewhere. Still, I am, on the other hand, conscious that there is for almost all the young men I have been speaking of turned out by our public schools a round hole somewhere in the Empire if they could only find it. And it is, therefore, a difficulty which must be solved some day by some statesman, some legislator, or some educationist: the difficulty of finding some adaptation of the peg for the hole throughout the British Empire. As regards physique, at any rate, I can testify to this. I happened to be watching a cricket match here the other day—I speak under the correction of the captain whom I see present—when I saw a young fellow, who measures so many inches that I could not help thinking that Frederick the Great's father, who stuck at nothing to procure tall soldiers, would have kidnapped that young man from the ground without demur. I can speak with thorough belief of the way in which old Epsomians are conducting themselves in the various avocations which they have chosen. We have here a most splendid teaching establishment, headed by my friend Mr. Smith-Pearse, we have the healthiest situation in the world, and if the College does not develop as it should or as it might it can only, I think, be due to the timidity of parents who believe that the counter attractions of Epsom may have some deleterious influence on the tender years of their sons. If my voice can reach them from here let them be sure that the race week is a period of monastic seclusion to the boys of Epsom College, that no contamination is allowed to reach them. They, I believe, never know the name of the winner of the Derby until they have separated for the vacation when they learn it from tradition at home. And for those who intend to be medical men there is that rudimentary element of health, the Epsom well, which is supposed to have supplied Epsom salts to an admiring world. With these advantages, and without, so far as I know, any drawbacks, we may look cheerfully to the next jubilee.

ANNUAL DINNER OF THE EPIDEMIOLOGICAL SOCIETY.

THE fifty-fifth anniversary dinner of this society was held at the Grand Hotel, Trafalgar-square, London, W.C., on June 30th, the chair being occupied by the President, Dr. B. Arthur Whitelegge, C.B., His Majesty's Chief Inspector of Factories. There were also present Dr. E. F. Bashford, Dr. R. M. Beaton, Dr. W. A. Bond, Dr. G. S. Buchanan, Dr. H. T. Bulstrode, Dr. Dudley W. Buxton, Mr. Wolf Defries, Lieutenant-Colonel R. H. Firth, R.A.M.C., Mr. K. W. Goadby, Dr. W. J. Gow, Dr. W. H. Hamer, Dr. G. E. Herman, Mr. T. H. Kellock, Dr. T. N. Kelynack, Dr. H. R. Kenwood, Mr. John Langton (President of the Medical Society of London), Dr. R. Bruce Low, Dr. T. Glover Lyon, Dr. Hector W. G. Mackenzie, Mr. G. Millson, Sir Shirley F. Murphy, Dr. Arthur Newsholme, Colonel J. Lane Notter, R.A.M.C. (retired), Dr. J. Frank Payne, Sir Richard Douglas Powell, Bart., K.C.V.O., President of the Royal College of Physicians of London, Dr. H. Meredith Richards, Dr. James Robertson, Dr. John Robertson, Major Ronald Ross, C.B., F.R.S., Mr. W. N. Shaw, F.R.S., Mr. P. Sidney Spokes, Dr. R. D. Sweeting, Dr. John F. W. Tatham, Mr. D. Lewis Thomas, Dr. G. L. Turnbull, Mr. A. C. Waters, and Dr. Dawson Williams.

After the usual loyal toasts, "The Medical Departments of His Majesty's Forces" was proposed by Dr. PAYNE, who, in speaking of the Medical Department of the Navy, referred to the testimonial which Admiral Rodney gave to Gilbert Blane, physician to the English fleet, who was a candidate for a vacant physiciancy at St. Thomas's Hospital. The admiral wrote: "It was owing to Dr. Blane that the fleet at my command was kept in a condition ready to attack the public enemy." Dr. Payne had no doubt that an admiral of to-day would have to write in the same terms of the present Medical Department were the necessity to arise.

Colonel **LANE NOTTER** responded.

Dr. **DAWSON WILLIAMS**, in proposing "The Medical Societies," of which he observed there were 22, drew attention to the economy which would accrue could a satisfactory scheme of amalgamation be devised. He expressed the opinion that the poor attendances of the meetings of the medical societies were largely due to the fact that the proceedings were reported in the medical papers and he suggested the desirability of the exclusion of the medical press if the attendances were to be improved.

Sir **RICHARD DOUGLAS POWELL**, in responding, thought that these bad attendances were a growing evil and that some form of concentration was eminently desirable. He was not, however, in agreement with the proposer of the toast as to the exclusion of the medical press. In the old days reporting was very imperfect but now that the reporting was all that could be desired it was essential that the practice of thus recording the proceedings should be continued.

Mr. **LANGTON**, with whose name the toast was also coupled, pointed out that chaos, as regards the medical societies, began as far back as 1808. He hoped, however, that although amalgamation in practice was a much more difficult matter than in theory and was beset by many difficulties, financial and other, a scheme would be presented within the next few weeks which would afford a means of escape from the present unsatisfactory state of affairs.

Colonel **FIRTH** proposed "The Visitors" and Major **ROSS**, in responding, expressed the great pleasure which it had afforded him to find the brilliant researches of Colonel D. Bruce recognised in that day's birthday honours. Commenting generally upon investigations in the tropics, Major Ross accentuated the importance of encouraging the numerous younger men who for very little pay indeed were content to go forth on missions which were by no means free from risk and which in some instances had resulted in the death of the workers. He would like, too, to see more energetic action on the part of the Government with regard to the many places where malaria was at present rife but from which without serious difficulty it might be eradicated. In his view the medical profession was somewhat too backward in pressing the claims of science upon the public.

Mr. **SHAW**, the recently appointed director of the Meteorological Office, also acknowledged the toast and in discussing the relationship between epidemiology and meteorology, confessed that there was some truth in the statement made by the schoolboy who, when asked as to the nature of a barometer replied: "A barometer is an instrument shaped like a banjo; it is meant to foretell the weather *but it cannot foretell it for long*." Although the Meteorological Office issued forecasts with regard to the weather which had an undoubted value there was nevertheless force in the schoolboy's criticism. Mr. Shaw thought that possibly the epidemiologist had been in the past somewhat too prone to associate outbreaks of disease with meteorological events which had immediately preceded the outbreak, whereas possibly such an outbreak might be partly due to an accumulation of influences some of which had been operative several months previously. As a suggestion in this direction he might make reference to the fact recently drawn attention to by him in the *Times* that the wheat crop of any given year was due, not to the weather of the preceding spring, but to the amount of rainfall in the preceding autumn—i.e., to an event which happened some ten months before the result, *quâ* the wheat yield, was apparent. It had been calculated that every inch of rainfall by washing out the nitrates from the soil was responsible for a loss of one and a quarter bushels of wheat per acre in England, an amount which in the mass meant a loss of some £300,000 to the farmer.

Dr. **TATHAM**, in proposing "The Epidemiological Society," took the opportunity of thanking the members for the honour which they had recently conferred upon him in electing him to fill the presidential chair in succession to Dr. Whitelegge. Dr. Tatham looked forward to the time when his office, the General Register Office, by furnishing general statistics as regards sickness, would be in a position to afford to the Epidemiological Society very considerable additional assistance in its researches.

Dr. WHITELEGGE, in replying and in discussing the enormous advances made in epidemiology since the foundation of the society in 1850, drew attention to the circumstance that curiously enough both the epidemiology and the bacteriology of the common cold had been practically neglected notwithstanding the fact that the indirect effects of this communicable condition must exercise a very substantial effect both on the sickness and mortality records. Research, however, extended first in one direction and then in another, and the most remarkable discoveries of recent years had doubtless been in relation to the part played by the insects and protozoa in the distribution of disease. The society was, he was glad to report, in a decidedly flourishing condition. The attendances at the meetings had been better than ever before and the papers and discussions had been of a very high order. He alluded in eulogistic terms to the services rendered to the society by the honorary secretaries and treasurer—a compliment which was suitably acknowledged by Dr. BULSTRODE, Dr. HAMER, and Dr. SWEETING.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are some of the principal amounts, additional to those already announced in THE LANCET, received at the Mansion House up to Wednesday evening, when the sum paid in came to £40,000:—

	£	s.	d.
St. Paul's Cathedral, with additions	4900	0	0
Christ Church, *Lancaster-gate*	1312	0	0
St. Jude's, South Kensington	505	0	0
St. Paul's, Onslow-square	396	0	0
All Saints, Ennismore-gardens	391	0	0
St. Paul's, Wilton-place, and St. Mary's, Graham-street	361	0	0
St. George's, Hanover-square	324	0	0
St. Mary's, Bryanston-square	320	10	0
Church of Annunciation, Marylebone	248	0	0
Union Chapel, *Islington*	236	0	0

THE IMPERIAL CANCER RESEARCH FUND.

THE fourth meeting of the general committee of the Imperial Cancer Research Fund was held at Marlborough House on July 5th and was presided over by H.R.H. the PRINCE of WALES, the President of the Fund.

Those present included Lord Strathcona, Sir William Broadbent, Sir William S. Church, Sir Henry G. Howse, Sir Alfred Cooper, Mr. James Coats, Mr. H. L. Florence, Mr. H. J. Read, Dr. J. F. W. Tatham, Mr. J. Tweedy, President of the Royal College of Surgeons of England, Dr. J. Rose Bradford, Mr. H. T. Butlin, Mr. W. Watson Cheyne, Professor J. R. Dewar, Mr. J. Langton, Mr. R. Littlejohn, Professor J. McFadyean, Professor A. E. Mettam, Mr. J. A. Mullens, Dr. P. H. Pye-Smith, Dr. T. T. Whipham, Professor G. Sims Woodhead, Mr. R. Brudenell Carter, Mr. E. R. Frere, Mr. Henry Morris (honorary treasurer), Dr. E. F. Bashford (general superintendent of the research work), Dr. W. Cramer, and Mr. F. G. Hallett (secretary).

Sir WILLIAM CHURCH, Bart., K.C.B., chairman of the executive committee, moved the adoption of the annual report and in doing so gave an account of the proceedings of the executive committee and of the scientific investigations during the year. "Cancer investigation," he said, "has been carried out during the year in close conformity with the plan determined on in the second year of our research and may be conveniently described as falling under three main heads—the statistical, the histological, and the experimental. Additional data have been accumulated since, confirming the opinion that cancerous growths cannot be associated with any peculiarities of diet. Further evidence has been obtained that in considering the frequency of the occurrence of cancer due regard must be paid to the individual ages of the population under consideration and when it occurs in young subjects to the organs in which the disease manifests itself, cancer in young persons occurring for the most part in tissues and organs which lose their functional activity in early life and normally undergo degeneration and more or less complete absorption. The continued tabulation of the cases of malignant growth in the metropolitan hospitals, in which the presence of cancer has been proved by microscopical examination, has confirmed the opinion that in cases of internal growths the errors of diagnosis, even when under the charge of most experienced and accomplished observers, are much greater than would be expected and in no small degree explain many of the reputed cases of cure. Dr. Tatham of the General Register Office has had the national statistics of malignant disease rearranged in a manner which will enable them to be compared with the figures obtained from hospitals and other sources and thus afford a broader basis for the control of statistics. Histological, cytological, and experimental investigations have been vigorously carried on and have yielded results of remarkable interest, raising questions in connexion with malignant disease which had hardly been suspected before. The results which had been obtained in mice pointed to the necessity for yet more closely studying the processes of cell multiplication, for in the means which permit this to continue incessantly appears to lie the mystery we are in search of. Certain cancerous tumours are found occurring sporadically in mice which can be transplanted into other mice. In this way it has been found possible to perpetuate a malignant growth through successive generations of mice and thus obtain material for observation and study. Every transplantation does not succeed, very far from it, and at present we are not in a position to say what determines the success or failure of the experiment. Slight racial differences in the mice seem to have a distinct bearing on the success of transplantation. For example, Professor von Leyden of Berlin was kind enough to send us a live mouse which had a tumour which had been transplanted through three generations in Berlin wild mice, together with 20 Berlin wild mice. 47·3 per cent. of the transplantations made into the 20 Berlin wild mice were successful, whilst the transplantations into London wild mice gave only 1·4 per cent. of success, and in London tame mice the proportion (0·54 per cent.) was even less. When the initial difficulty of transplanting a tumour from one strain of mice to another has been overcome the percentage of success reaches approximately that which obtains when mice of the same strain are used. Careful examination of transplanted tumours has shown that a continuous power of growth is manifested by the transplanted cells and that the new growth originates from them and not from the cells of the host irritated or stimulated by the transplanted material; the reaction caused in the tissues of the host affords the means by which the transplanted cells are nourished. Another fact which is of great importance is that whilst in mice, as in man, spontaneous malignant growths occur in the aged rather than in the young, transplanted growths flourish as well, or better, in young and vigorous mice. I will not weary you with a description as to the differences between these mouse tumours and what are called infective granulomata; sufficient to say here that in the infective granulomata it is the cells of the infected animal which take on abnormal growths. It has long been recognised that malignant growths produce their injurious effects by their power of continuous cell multiplication. The artificial propagation of malignant growths is a demonstration of this power of cell division, for by its means we have from a single mouse tumour produced an amount of tissue equal in bulk to more than a thousand mice. As bearing on the infectiousness of cancer, it may be mentioned that large numbers of healthy mice have been kept for long periods in the same cages with mice suffering from both sporadic and inoculated tumours and yet in no single instance did the malignant growth occur in an uninoculated mouse. In connexion with the treatment of malignant growths a large amount of experimental work has also been done. The action of normal sera upon cancer cells outside the body does not prevent their growth when transplanted into the body, but subjecting them to the action of an immunising serum has in some cases deprived the cells of the power of growth, but no definite action has yet been observed when an immunising serum has been injected into a mouse suffering from cancer. The action of radium and radio-active solutions has been carefully studied and there is no doubt that both at times exert an influence on the growth and development of both normal and tumour tissues. No evidence, however, has yet been obtained that radium emanations have any selective or special action on tumour tissues, whilst the amount of radio-active solutions which is necessary to produce any action on the tissues is far in excess of what can be introduced into the body with safety. The Research Fund is indebted to Sir William Ramsay for preparing and placing radio-active solutions at its disposal. The expenses of the research must increase if we are to keep the highly trained staff which is necessary. We have lost the services of Dr. Cramer, who has accepted the appointment of Lecturer on Physiological Chemistry at Edinburgh; whilst Dr. Murray, I am happy to say, would not leave us, although offered a more valuable appointment as director of the Liverpool Cancer Research Fund. It places our research in very disadvantageous circumstances if we are unable adequately to remunerate the services of highly skilled members of our staff whose loss we should be unable to replace. Our work during the past year has been greatly aided by the collaboration of foreign investigators, more especially by Professor Borrel of the Institut Pasteur, Professor Jensen of Copenhagen, and Professor von Leyden and Dr. Michaelis of the German Cancer Committee. Very valuable assistance has also been afforded by the India, Foreign, and Colonial Offices, as well as by other public offices and bodies, and by private individuals, both in this country and abroad, but I regret to say that the unaccountable action of the postal authorities in refusing to transmit perfectly innocuous postal packets addressed to the research will disorganise the arrangements which, through the coöperation of the India, Foreign, and Colonial Offices, had been made for the transmission of specimens from India, the colonies, and other foreign countries. In conclusion, I think I may venture to say that the cytological and experimental work done during the past year marks a real progress in our knowledge of the mode of growth in certain forms of malignant disease. The malignancy of cancer appears to consist in the inherent power the cells possess of division and multiplication. If we can find out the nature of this apparently unlimited growth it is not unreasonable to hope that we may be successful in obtaining means for checking or limiting their proliferation and thus neutralising their malignancy."

Mr. TWEEDY, in seconding the motion, said he thought that all the subscribers to the Fund on reading the general report, and more particularly the scientific reports, must feel that this body was making distinct progress in the solution of the great mystery of the origin and the nature of cancer. Many of those who did not understand the processes of scientific investigations might desire that they should attain their goal at one step, as it were, but knowledge was not to be gained in this way. Whether they would ever attain the goal aimed at, or when, no man living could say, but he was convinced that this body for the investigation of the causation of cancer was proceeding by the right method—the method of science—which must give them true knowledge so far as it went. In the end he hoped that they would obtain the knowledge which they all so much desired.

The report was unanimously adopted.

Lord STRATHCONA proposed a vote of thanks to the chairman and members of the executive committee, the subcommittees, the honorary treasurer, and others who had assisted in the work of the Fund during the past year and expressed the gratification of the supporters of the Fund at having Sir William Church at the head of the executive committee.

Mr. LITTLEJOHN seconded the motion which was carried unanimously.

Sir WILLIAM BROADBENT proposed a motion as an amendment to the scheme of the Fund whereby the executive committee would be able to retain the services of valuable *ex-officio* members, when their terms of office having expired, their membership of the executive committee of the Fund also ceased. The amendment also proposed to add to the executive committee other persons likely to assist in the management of the Fund, for whose election at present no means were provided.

The motion was seconded by Mr. LANGTON and was unanimously agreed to.

Mr. MORRIS, in moving that the best thanks of the meeting be given to His Royal Highness for presiding and for permitting the meeting to take place at Marlborough House, said that they were all aware that from the inception of this scheme the hearty sympathy and goodwill of His Royal Highness had been given towards the establishing of a cancer investigation. As soon as the scheme was sufficiently advanced the Prince of Wales accepted the presidency, and on every occasion when opportunity had offered he had been good enough to make a gracious and encouraging mention of the work and of the objects of the Fund.

Mr. FLORENCE seconded the motion which was carried with acclamation.

The PRINCE OF WALES, in reply, said: My Lord and Gentlemen,—I beg to thank Mr. Henry Morris and Mr. Florence for the kind words they have used in proposing and seconding this vote and I thank you all sincerely for the way you have received it. I am very glad, as your President, to meet here again the members of the general committee of the Imperial Cancer Research Fund and to hear the very satisfactory record of the past year's work. Naturally, you will not expect me to touch upon the highly technical subjects dealt with in the annual report and in Dr. Bashford's scientific reports which have been circulated among you. But we all can recognise in them much evidence of laborious and careful investigation and of sure progress. These reports cover a very large field of investigation and show that no line of inquiry, however unpromising, is being overlooked. The search after fresh facts has been stimulated by the rejection during the past three years of certain fallacies which previously obscured the true problem and have now been exposed. One result obtained shows that cancer is not transferable from one individual to another as if it were an infectious disease. The destruction of preconceived ideas of the origin of cancer has cleared the way for further advance, while the number of hitherto unsuspected facts certainly gives hope of final success. The researches in the various British colonies and protectorates continue to yield information of increasing value and prove that the investigation is truly an Imperial one. Last year I mentioned that India had recently been included in the scope of inquiry. Since then India has contributed additional and interesting facts. Amongst the various races and castes of that great empire, differing so widely in customs, mode of living, and diet, cancer has been shown to be not uncommon. It is found in vegetarians as well as in those who eat fish and meat. Increasing interest in the question is being manifested in the larger self-governing colonies It is important to notice that owing to our possessions throughout the globe we are in a more favourable position than other nations for studying this disease, which manifests itself irrespectively of the varying conditions of life. These opportunities are being fully utilised not only for our own information but to the advantage of the scientific investigators of other nations less favourably situated. Many reputed remedies for cancer have been sent to our laboratories during the past year for examination not only from this country but from India, Australia, South Africa, and America. Unfortunately any value that they may have possessed to those who believed in them has been based upon the application of the term "cancer" to diseases which are not true malignant new growths. They have not survived the test of scientific examination. It is gratifying to know that our work is being carried out in harmonious conjunction with that of French, German, and American scientists. I feel sure that the committee share my feelings of satisfaction in having secured the retention of Sir William Church's services on the executive committee, of which he has been re-elected chairman. We have to acknowledge with gratitude the kindness of the Royal College of Physicians and the Royal College of Surgeons in placing their laboratories at the disposal of the Fund. In conclusion, I have to assure the executive committee, general superintendent, treasurer, and secretary of my deep appreciation of the eminent services rendered by them in their steadfast endeavours towards the solution of what still remains one of the greatest problems of human life.

The proceedings then terminated.

ASYLUM REPORTS.

Ayr District Asylum (Annual Report for 1904).—The report of the medical superintendent, Dr. C. C. Easterbrook, states that the average number of patients daily resident was 517. The admissions numbered 140. 56 were discharged recovered, the recovery rate being 44 8 per cent. on the admissions minus transfers from other institutions and minus admissions from private care of congenital and chronic cases. Ayrshire, it appears, stands twenty-eighth amongst the 33 counties of Scotland arranged according to the prevalence of insanity in them and is therefore one of the sanest. Dr. Easterbrook goes exceptionally fully and with copious statistical tables into the causation of insanity in the admissions. Insanity in the family was acknowledged in 36 per cent. of the males and 44 per cent. of the females. "Insane and neurotic constitution" was present in 40 per cent., and in 21 per cent. there had been one or more previous attacks of insanity. Alcohol was the cause of the attack in only 13·7 per cent., as against 25·9 per cent. in the previous year. The decrease in alcoholic cases mainly accounts for a fall below the average of the admissions for 1904 and this decrease is explained by the depression of trade during 1904. The deaths during the year numbered 59 and consent to necropsy was only refused in six. Only seven deaths occurred from pulmonary tuberculosis. The infirm and acute wards of this asylum appear from the report of the Commissioners in Lunacy to be overcrowded greatly, but a new hospital is to be erected.

Surrey County Asylum, Brookwood (Annual Report for 1904).—From the report of Mr. James E. Barton, the medical superintendent, it appears that the average number resident in this asylum during the year was 1309. The admissions numbered 346 (including 35 transfers from other asylums and two found "not insane"), the discharges 161, and the deaths 129, this last figure giving a proportion of 9·86 per cent. on the daily average number resident, which is slightly lower than the average rate in English asylums. The type of insanity in the admissions was, as for several years past, very unfavourable, about 25 per cent. only being considered to have reasonable prospect of recovery. Out of 22 cases of general paralysis, which were all that occurred amongst the 346 admissions, a history of syphilis was obtained in eight. Hereditary predisposition is stated to have existed in only 74 cases (21 per cent, or 24 per cent. excluding transfers and those "not insane"), which is certainly an unusually small proportion. Figures on this point are notoriously untrustworthy, depending as they do upon the statements of patients' relatives. The recovery rate, calculated as is usually done, was 30·64 per cent. on the admissions The Commissioners in Lunacy report that the asylum is maintained in very good order. Some important improvements to meet the contingency of an outbreak of fire have been carried out. The weekly charge for home patients is 12*s.*, which is high for a county asylum.

Looking Back.

FROM

THE LANCET, *SATURDAY*, July 7, 1827.

The answers to some of the queries propounded by the Royal Commissioners[1] are extremely curious and amusing, as showing the coolness with which these Northern Professors assume and defend the most ridiculous of all absurdities. They distinctly state, that a man's chance of success in his profession is in the inverse ratio of his attainments—directly opposed to his merits and his talents! One of them, Dr. Alison, Dean of the Faculty of Medicine, mentions this as "a general fact, of which evidence can be adduced!" And how does the reader think this "general fact" is assumed? Why, on the ground that the general practitioners are more employed than the Edinburgh graduates, who, according to Dr. Alison, have a world of scientific attainments which the former are supposed to want! His graduates, he says, are oftener surpassed in practice by men who are their inferiors, than by men who are their superiors in general literature and science; he would say, *much oftener*. But assuming all this to be true, that in the lottery of physic the chance of a man who holds ten tickets is decidedly worse than that of one who is possessed but of five—which by-the-bye is absurd—it does not follow that a person taking a doctor's degree, which is in some respects a *literary* degree, should not be grounded in literature and general science; for wanting these the degree of *doctor* is as much abused as his Majesty's head upon a bad shilling. What would they have? They surely do not pretend that practical medicine can be best learned at Edinburgh, and they do not wish to enforce any great degree of literary study; yet, forsooth, the *gradus doctoris* is to be the stamp of superior excellence in both! The day will come, it has already dawned upon us, when the empty distinctions of colleges, which were probably of some use during the dark ages, shall be valued as they merit, just as the glimmering midnight-taper is unseen or disregarded in the meridian sun; but in the meantime we cannot see the difference between an *unlearned* doctor, a doctor unacquainted with Greek and Latin, polite literature, and the arts, which Dr. Alison thinks he may be—and the disgraceful, but well known Eady, neither of them being what he pretends to be, nor what the ignorant give him the credit of being. As long as a knowledge of Greek and Latin is expected from a gentleman, so long, at least, will it be from the physician, and there are many reasons, strictly professional, which might always render such knowledge desirable, although no invidious contrast were drawn and no such acquirements expected; of course it is a great error to give more attention to the extra-professional departments of literature and science than can be conveniently spared; but as these things are usually studied in early life, and furnish a calm and delightful retreat from the severer studies, anxieties, and occupations inseparable from our calling, we, for our parts, (Dr. Alison may think as he pleases), should be very loth to have been altogether without them.[2]

---

[2] Excerpt from leading article.

ROYAL INSTITUTION.—A general monthly meeting of the members of this institution was held on July 3rd, Sir James Crichton-Browne, treasurer and vice-president, being in the chair. Baroness Gray was elected a member. The special thanks of the members were returned to Sir Andrew Noble, K.C.B., F.R.S., for his donation of £100 to the fund for the promotion of experimental research at low temperatures, and to Mr. Rollo Appleyard for his gift of a portrait of the late Professor J. D. Everett, F.R.S., M.R.I.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

County Borough of St. Helens.—The St. Helens milk depôt has not, Dr. J. J. Buchan reports, been extensively patronised during 1904, although it was kept prominently before the public during that time. The number of children using the milk continuously was 160 and more than half of these—i.e., 86—were, when first taken to the depôts, suffering from gastro-intestinal disorders consequent upon hand-feeding. This point is a very important one, as it has a distinct bearing upon the statistics furnished in the following table:—

Year.	Number of children on books.	Death-rate per 1000 among children at depôt.	Infantile death rate.
1899	232	103	157
1900	332	102	188
1901	282	106	175
1902	200	82	167
1903	183	54	137
1904	160	68	174

Dr. Buchan infers from these figures that "had the ordinary death-rate in the borough in each year occurred among the users of the milk the deaths for these six years would have been increased by 109; in other words, there are 109 children living now who would have been dead but for the infant milk depôt." Without wishing for a moment to detract from the good work done by the depôt we are afraid that this method of presenting the gain is a little too optimistic. There are, of course, many critics who would take exception to these figures altogether and who would say that the children are selected in that they belong to mothers who have sufficient care for their lives to take them to the depôt at all, whereas many of the mothers who do not thus take their children belong to the neglectful class amongst which there is naturally a high infantile mortality. But this criticism seems to be met in the present case by the statement that more than 50 per cent. of the children were suffering from gastro-intestinal disorders. Be this as it may, we are hardly justified in asserting that the 109 children who did not die while they were attending the depôt are still alive. To say this is to imply that all children die from errors in diet. The main difficulty in connexion with the St. Helens depôt is that of distribution at convenient centres, and apparently the Dairymen's Association, which was approached on the subject, was not able to render assistance. The amount falling on the rates by the operations of the depôt during 1904 was £176 3*s.* 7*d.*

Metropolitan Borough of Woolwich.—This borough council now maintains three beds at Peppard Common sanatorium but Dr. Sidney Davies states that as regards cure sufficient time has not elapsed to form a trustworthy opinion. He adds, however, that of 17 patients who have been in the sanatorium three are still at the institution and three have died. Of the remaining 11 all were much improved in weight and other ways by their stay. Two are at home apparently quite well—one is at work and the other is seeking work. Four have relapsed since their return. Of these one is now in the Brompton Hospital, one is at work but getting worse, and two are being treated at home. In three cases the treatment did not arrest the disease, although it improved the patient's general condition. Dr. Davies thinks that, although isolation in this sanatorium may prevent the infection of other members of the same family and afford education in curative and preventive measures, it cannot be expected that three months' treatment will, as a rule, complete the cure. For this he regards six months at least as being necessary.

County Borough of Croydon.—Dr. H. Meredith Richards makes a contribution in his current annual report to the discussion as to the value, if any, of isolation hospitals for scarlet fever. He divides the cases which occurred in 1904 into two groups. In the "hospital" group—i.e., in the group in which the patients were isolated in hospital—there were 298 susceptible children (under 14 years of age) left at home after removal of the primary case or cases. In the "home" group there were only 50 such susceptible children at home on the notification of the primary case or cases. In the "hospital" group 63, or 21·2 per cent. of the susceptible children developed scarlet fever after removal to hospital of the primary case, while in the "home" group 19, or 38 per cent., developed the disease. Dr. Richards regards these figures as showing the advantage of hospital isolation and he points out that the majority of the "home" group consisted of patients who could be satisfactorily nursed at home. Certainly the figures are of value but they would, we think, have been more trustworthy had the susceptible children been split up into age groups and the incidence on each age group for both classes furnished. Dr. Richards does not think highly of the midwife. He tells us that during 1904 the appliances of the Croydon midwives were inspected and that in nearly every instance the cases, mainly through ignorance as to the meaning of the words used in the rules, were improperly kept. Several of the midwives being unable to write had to have their forms filled up by deputy. Many of the women did not possess the instruments which they are required to take with them, but this omission Dr. Richards does not regret as, in his opinion, the women are totally ignorant of the uses to which to put the instruments. Dr. Richards has been appointed medical adviser to the education authority, his duties being (*a*) to report on the sanitary condition of the schools and the general health of the scholars; (*b*) to examine blind, deaf, and defective children; (*c*) to examine plans for altering or erecting school buildings; (*d*) to examine pupil teachers selected for appointment; (*e*) to examine truant children; (*f*) to visit any employé absent through illness; (*g*) to examine children stated to be physically unfit to attend school; and (*h*) to advise the committee when required to do so.

County Borough of Bournemouth.—The desire of the people of Bournemouth to consume what they think is a "rich" milk is well illustrated by the fact that 64·8 per cent. of the samples purchased and examined during 1904 were artificially coloured with annatto. We should have thought that the educated class which forms such a substantial portion of the total population of Bournemouth would have had more discrimination in the matter of natural milk. It is, however, on the other hand, gratifying to read that for the first time for several years all the samples of milk analysed were found free from preservatives; presumably formalin was looked for as well as boric acid.

Edmonton Urban District.—Dr. A. W. J. MacFadden, commenting upon the notification of pulmonary tuberculosis, remarks, "Compulsory notification under the Act of 1899 has in most cases been preceded by a probationary period of voluntary notification during which the benefits of the system have become apparent and its opponents have been reconciled to the inclusion of phthisis in its proper category—namely, that of the compulsorily notifiable diseases." But it is news to us that pulmonary tuberculosis is a compulsorily notifiable disease in any place other than Sheffield, and even there the disease is not subject to any of the penal clauses of the Public Health Act. Perhaps Dr. MacFadden will kindly furnish in his next annual report a list of the places in which the disease in question is notifiable. The Edmonton district council has provisionally arranged to take up three beds at the proposed Middlesex sanatorium. It seems almost a pity that some of the beds at the Mount Vernon Sanatorium at Northwood cannot be utilised by the sanitary authorities in Middlesex.

Plympton St. Mary Rural District Council.—Mr. S. Noy Scott, speaking of sanatoriums for consumption, says, "Since my last report another year's experience has been gained of the 'sanatorium treatment' and I am forced to state that in spite of much good that can legitimately be assigned to such institutions, yet there seems to be a steadily growing opinion that the great expectations which were at first formed of them were exaggerated ones, and that the time has come for a thorough investigation of the whole question. No one doubts that the methods on which sanatorium treatment is based—viz., unlimited fresh air, abundant feeding, and good general hygiene—are absolutely right, but many accurate observers are expressing the opinion that these methods can be more easily obtained by a much less costly and extravagant system than is at present in vogue, and, further, that in building sanatoria we are using money and energy which could be far more beneficially spent in such prime preventive measures as well-built cottages on suitable sites." Seeing that there is a sanatorium for Devonshire near Brent it would have been perhaps more helpful had Mr. Scott told us something as to the after-history of the cases treated at that institution.

Borough of Eastbourne.—Dr. W. G. Willoughby thinks that a sanatorium for consumption should be used largely on educational lines and not merely as an institution to replace the workhouse infirmary. Admission to a sanatorium should, in his opinion, be limited to ratepayers of some years' standing and he evidently sees that otherwise consumptive patients might be attracted to Eastbourne were a sanatorium erected there. He points out, however, in connexion with the question of providing such an institution that "the decrease in consumption commenced long before sanatoria became the fashion, by improved sanitation, and after all the object of a sanitary authority should be to make every house and the whole borough as sanitary as a sanatorium." Perhaps this is a somewhat extreme view, since the fresh country air is one of the essentials of the sanatorium treatment and this is difficult to procure in an existing town.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8496 births and 379 deaths were registered during the week ending July 1st. The annual rate of mortality in these towns, which had been 13·5, 13·4, and 13·0 per 1000 in the three preceding weeks, further declined to 12·7 per 1000 last week. In London the death-rate was 12·0 per 1000, while it averaged 13·0 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·8 in Willesden, in Hornsey, in Leyton, and in Handsworth (Staffs), 7·2 in East Ham, 7·5 in King's Norton, and 7·6 in East Ham and in Walthamstow; the highest rates were 17·5 in Stockport and in Tynemouth, 17·6 in Blackburn, 18·1 in Wigan, 19·1 in Merthyr Tydfil, 20·7 in Middlesbrough, 21·2 in Sunderland, 23·1 in West Bromwich, and 23·9 in Stockton-on-Tees. The 3793 deaths in these towns last week included 371 which were referred to the principal infectious diseases, against 413, 355, and 348 in the three preceding weeks; of these 371 deaths, 120 resulted from measles, 89 from diarrhœa, 72 from whooping-cough, 39 from scarlet fever, 32 from diphtheria, 18 from "fever" (principally enteric), and one from small-pox. In Tottenham, Leyton, Brighton, Southampton, Burnley, Halifax, and in ten other smaller towns, no death from any of the principal infectious diseases was registered, while they caused the highest death-rates in West Bromwich, Bootle, Warrington, Sheffield, Middlesbrough, and Sunderland. The greatest proportional mortality from measles occurred in West Bromwich, Warrington, Barrow-in-Furness, Sheffield, and Sunderland; from scarlet fever in Bootle; from whooping-cough in Oldham, Preston, and Middlesbrough; and from diarrhœa in Bootle and Rhondda. The mortality from diphtheria and from "fever" showed no marked excess in any of the large towns. One fatal case of small-pox was registered in London but none in any of the large provincial towns. The Metropolitan Asylums Hospitals contained four small-pox patients at the end of last week, against nine, seven, and six at the end of the three preceding weeks; one new case was admitted during the week, against three, three, and one in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 2285, 2356, and 2427 on the three preceding Saturdays, had further increased to 2473, on Saturday, July 1st; 334 new cases were admitted during the week, against 269, 292, and 325 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 191, 189, and 144 in the three preceding weeks, further declined last week to 140, and were six below the number in the corresponding period of last year. The causes of 36, or 1·0 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Manchester, Leeds, Hull, Newcastle-on-Tyne, and in 51 other smaller towns; the largest proportions of uncertified deaths were registered in Hanley, Liverpool, Sheffield, Sunderland, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal

Scotch towns, which had been 16·4, 15·7, and 15·1 per 1000 in the three preceding weeks, rose again to 16·5 per 1000 during the week ending July 1st, and was 3·8 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·2 in Perth and 14·7 in Edinburgh and in Leith, to 18·2 in Glasgow and 19·3 in Greenock. The 555 deaths in these towns included 31 which were referred to whooping-cough, 17 to measles, 14 to diarrhœa, two to "fever," and one to diphtheria, but not any to small-pox or scarlet fever. In all 65 deaths resulted from these principal infectious diseases last week, against 62, 74, and 60 in the three preceding weeks. These 65 deaths were equal to an annual rate of 1·9 per 1000, which was 0·7 per 1000 above the mean rate last week from the principal infectious diseases in the 76 large English towns. The fatal cases of whooping-cough which had been 23, 29, and 18 in the three preceding weeks, rose again last week to 31, of which 22 occurred in Glasgow, five in Edinburgh, and two in Greenock. The deaths from measles, which had been 17, 26, and 18 in the three preceding weeks, further declined to 17 last week, and included ten in Glasgow, five in Edinburgh, and two in Perth. The fatal cases of diarrhœa, which had been 15 in each of the two preceding weeks, decreased last week to 14, of which eight were registered in Glasgow, two in Dundee, and two in Leith. The deaths from "fever," which had been three, two, and three in the three preceding weeks, declined to two last week and were both registered in Greenock. The deaths referred to diseases of the respiratory organs in these towns, which had been 89, 63, and 74 in the three preceding weeks, declined again last week to 68, and were 12 below the number in the corresponding period of last year. The causes of 16, or nearly 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·3, 17·2, and 17·9 per 1000 in the three preceding weeks, declined again to 14·9 per 1000 during the week ending July 1st. During the past 13 weeks the death-rate has averaged 20·4 per 1000, the rates during the same period being 14·3 in London and 16·1 in Edinburgh. The 108 deaths of persons belonging to Dublin registered during the week under notice were 22 below the number in the preceding week and included seven which were referred to the principal infectious diseases, against five, three, and six in the three preceding weeks; of these, two resulted from measles, two from diarrhœa, and one each from diphtheria, from whooping-cough, and from "fever," but not any from small-pox or scarlet fever. These seven deaths were equal to an annual rate of 1·0 per 1000, the death-rates last week from the principal infectious diseases being 1·1 in London and 1·7 in Edinburgh. The deaths from measles, diphtheria, "fever," and diarrhœa corresponded in each case with the numbers in the preceding week; one fatal case of whooping-cough was registered, against two, two, and none in the three preceding weeks. One inquest case and two deaths from violence were registered; and 42, or more than a third, of the deaths occurred in public institutions. The causes of seven, or more than 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Fleet Surgeon Francis Austen Jeans has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in His Majesty's Fleet (dated May 27th, 1905).

The following appointments are notified:—Fleet Surgeons: G. D. Twigg to the *Victory* and P. B. Handyside to Chatham Hospital. Staff Surgeons: S. T. Reid to Chatham Hospital; J. C. Durston to the *Flora;* and R. J. MacKeown to the *Vivid.* Surgeons: P. W. MacVean to the *Niobe;* A. A. Forrester to Chatham Hospital; H. W. Hull to the *Pathfinder on commissioning;* J. H. Jones to the *Pyramus;* W. M. Keith to the *Eclipse;* and W. L. Hawkins, lent to the *Speedy.*

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel L. E. Anderson is appointed to the medical charge of the Cambridge Hospital, Aldershot, and to command No. 1 Company, vice Lieutenant-Colonel H. W. Hubbard. Major J. D. Ferguson, D.S.O., is appointed second-in-command of the Depôt and Training School, Aldershot, vice Major F. J. Greig.

INDIAN MEDICAL SERVICE.

Bengal: Majors to be Lieutenant-Colonels (dated April 1st, 1905): Francis James Drury, Herbert Jekyl Dyson, Frederick Arthur Rogers, D.S.O., and Edward Richard William Charles Carroll.

The King has approved of the retirement from the service of the undermentioned officers:—Surgeon-General George William Robertson Hay (dated Dec. 27th, 1904); Colonel Charles Henry Joubert (dated March 29th, 1905); Lieutenant-Colonel George Spiers Alexander Ranking (dated May 30th, 1905); Lieutenant-Colonel George Tucker Thomas (dated June 26th, 1905); Lieutenant-Colonel Arthur James Sturmer (dated April 12th, 1905); Lieutenant-Colonel Cooverjee Cowasjee Vaid (dated May 18th, 1905); and Lieutenant-Colonel Upendra Nath Mukerji (dated Feb. 17th, 1905).

VOLUNTEER CORPS.

Rifle: 3rd Volunteer Battalion the Gloucestershire Regiment: Surgeon-Lieutenant (Surgeon-Captain, Army Medical Reserve of Officers) C. R. Browne to be Surgeon-Captain (dated July 5th, 1905). 5th (Glasgow Highland) Volunteer Battalion, the Highland Light Infantry: Surgeon-Lieutenant W. Ritchie to be Surgeon-Captain (dated July 5th, 1905).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Leicester and Lincoln Bearer Company: Alastair MacGregor to be Lieutenant (dated July 5th, 1905).

THE BIRTHDAY HONOURS.

In the list of birthday honours are the names of Surgeon-General Charles McDonagh Cuffe, C.B., who has been promoted to Knight Commander of the Bath; Surgeon-Major Thomas Egerton Hale, V.C., a survivor of the Crimean War, and Surgeon-General William Launcelot Gubbins, M.V.O., Principal Medical Officer of the Western Command in India, who have been made Companions of the Bath; and Colonel D. Bruce, F.R.S., R.A.M.C., and Lieutenant-Colonel and Honorary Colonel William Coates, R.A.M.C. Volunteers, who have been made Companions of the Bath in the Civil Division.

ROYAL VISIT TO MILLBANK MILITARY HOSPITAL.

On July 1st the King and Queen, accompanied by Princess Victoria, visited Millbank Military Hospital. Among those present to receive their Majesties were Surgeon-General A. H. Keogh, C.B., Director-General of the Army Medical Service; Major-General L. J. Oliphant, C.B., commanding the London District; Colonel A. T. Sloggett, A.M.S., C.M.G., Principal Medical Officer, London District; the Hon. Sidney Holland, and Sir Frederick Treves, C.B., K.C.V.O.

THE SCHOOLBOYS' REVIEW.

As regards the late review in Hyde Park of some 4000 or 5000 public school boys by the Duke of Connaught we may remark that the public had a good opportunity of seeing on that occasion the material which is ready to hand for forming a new line of defence. On both physical and moral grounds we hope that the time will come when it will be compulsory that every boy shall be taught the elements of military drill and shall learn the use of the rifle so as to fit himself to take part, if need be, in the defence of his country.

THE WAR IN THE FAR EAST.

There is no news of any special medical interest from the seat of war. That about the general state of affairs in Russia, and more especially as regards the actual condition of her naval and military forces, if taken in connexion with the recent unprecedented events at Odessa, Sevastopol, and elsewhere, has been so conflicting and liable to undergo such sudden and complete changes almost from day to day that it is impossible to form any accurate picture of the situation. It seems clear, however, that the forces of the Russian Government have been going through a very grave crisis and that, so far as Odessa at any rate is concerned, its inhabitants are only now emerging from a state of panic. It is settled that the Peace Conference is to take place but whether there is to be any armistice beforehand has not been decided. According to the latest accounts, Admiral Rojdestvensky is progressing favourably.

Several Russian medical men now in active service in the

Far East have asked the Minister for War whether those who have already been five years in service in that region may now have the option of returning to European Russia. The answer was in the negative unless such return were necessary for their recovery from wounds or illness, but owing to the undermanning of the medical service in the active army no one who was physically fit could be spared.

Correspondence.

"Audi alteram partem."

THE PRINCIPLES OF HEREDITY.

To the Editors of THE LANCET.

SIRS,—Mr. M. D. Eder's arguments in THE LANCET of June 17th, p. 1675, are somewhat difficult to follow. In his opening paragraph he paraphrases Dr. Archdall Reid and then seems to think he has controverted him. But to paraphrase is not to controvert.

The doctrine of evolution through natural selection is almost universally accepted by scientific men. Until recently it was universally believed that races which have long been exposed to a lethal and prevalent disease are more resistant than races which have been less exposed—for example, negroes as compared to Englishmen in relation to malaria and Englishmen as compared to Polynesians in relation to tuberculosis. It was believed also that South Europeans and Jews are more temperate than North Europeans in regard to alcohol and North Europeans than Red Indians; whereas natives of India, who have long used opium, are more temperate as regards it than Chinamen, who have used it less and who, on the other hand, are more temperate than Burmans, Polynesians, and Australian natives who have only recently made the acquaintance of the drug. Since, however, Dr. Reid attributed this acclimatisation (i.e., evolution) to natural selection Mr. Eder and one or two other gentlemen have discovered that it has no real existence. There is a direct conflict of evidence, but I am inclined to think that most people will believe, for example, that Englishmen are more resistant to tuberculosis than Polynesians, and Italians and Jews more temperate than Englishmen and Red Indians.

Mr. Eder's assumption that malaria has disappeared from England because Englishmen have become quite immune is totally unwarrantable. Dr. Reid clearly shows that no race can become *immune* to any disease to which it is susceptible through natural selection. He has assumed merely that negroes have become more *resistant* than Englishmen because they have suffered more. When Mr. Eder states that plague has been endemic in the East from a remote period does he mean that during this period the mass of the population has been continually exposed to infection? If he does not mean this his objection has no point. As a fact, the literature of the subject proves that plague is peculiarly an epidemic malady.[1] Apparently he disputes the statement that disease when epidemic is more terrible than when endemic. But, to take a couple of examples out of very many, the inhabitants of Great Britain flourished when both small-pox and measles were endemic. But a single epidemic of small-pox swept away 3,500,000 of the comparatively small population of Mexico, and quite recently (1876) more than a quarter of the inhabitants of Fiji perished during an epidemic of measles. In each case practically the whole population was stricken down, the sick were left untended, the business of the community was neglected, and famine followed.

Of course, Dr. Reid does not attempt to prove that the "non-inferiority" of certain races as compared to others is due to the use by the former of alcohol. Such a doctrine would contradict his entire teaching. No one has been so absurd as to suggest that the races which have used alcohol would have risen to the superman of Nietsche if they had not used it. The principle of parsimony has been thoroughly recognised by students of heredity, but they have recognised also the principle of correlation. Mr. Eder states that Dr. Reid has devoted little "space to the relation of the germ plasm to the environment." The actual truth is that many pages—one might almost say the whole work—are devoted to a consideration of this point. He implies that Dr. Reid advocates the sterilisation of the insane. Dr. Reid does not even hint at it. Both in his actual statements and in his implications Mr. Eder is inexcusably inaccurate throughout.

For myself, I can only say that I have read the work with great profit and pleasure and with entire conviction. It contains new matter and is original to a very unusual degree; it is lucidly, vividly, and interestingly written; it is the most considerable work on the subject that has appeared in the English-speaking world and the most comprehensive that has been published anywhere. It is not too much to say that no student of heredity, medicine, or sociology can afford to neglect it.—I am, Sirs, yours faithfully,

June 19th, 1905. D. WAUDBY.

To the Editors of THE LANCET.

SIRS,—Without any burning desire to confer a valuable service on science and humanity I willingly accede to Dr. Archdall Reid's request to amplify, so far as I can, my account of an epidemic of beri-beri in South America. The incident to which I referred took place at Puerto Alonzo, on the River Acre, a tributary of the Purus, in the year 1902-03. Puerto Alonzo is situated about 11° S. and 73° W. (I am writing without my papers and books to refer to). As to the number of Europeans who lived there and the number attacked I can speak positively because I saw them all, including the one who was still ill when I arrived (a Boer). I cannot furnish the exact numbers of the garrison nor of those attacked because I only reached the place towards the end of the siege; the returns were not my property and many of the papers were lost under the difficult conditions we were in. There is no exaggeration in the figures I give; the garrison was over 350 and more than 100 died from beri-beri. These figures were based on personal communication of the commanding officer and others to myself and on information I had from those who attended the sick. I must point out, however, that my observation was a particular one; having seen beri-beri in Europeans I could hardly have stated that it does not occur in Europeans. Dr. Reid writes that if my observation be correct there must be something in the waters of the Upper Amazon to account for the relative immunity of Europeans. Surely this is hardly one of these uses of the imagination in science which Tyndall advocated. Hypotheses by the score pass through the mind but I should think only those deserve publication that can be more or less readily verified by experiment.

Having had special opportunities of studying disease among the Jews during the last two years I repeat that this race within the limits of my observation suffers from alcohol pathologically like other races and that they are not moderate drinkers. To controvert my criticism of Dr. Reid's views on malarial immunity with a series of suppositions but strengthens my argument. It is asked why I suggested that there is no evidence to show that the malaria parasite which once flourished here was different from that in existence elsewhere. I suggested it precisely to meet by anticipation the views of those with whom conjectures pass for facts. I failed in my object. My experience of the South American people is to some extent confirmed in the very number in which you printed my letter. "Intemperance is general amongst the working-classes," observes the British Vice-Consul at Oruro, Bolivia.[1]

Please, Dr. Campbell, I did not repudiate the principle of natural selection. I should not be so impertinent. But really to-day the expression is quite devoid of meaning, seeing that it has so many. If Dr. Campbell tells me what he understands by the principle I shall be glad to repudiate his view, the editors' patience and my time permitting. Statistical evidence is alone in favour of the hereditary nature of tuberculosis; the affirmative view of so many great clinicians is of the same nature—i.e., so many cases where successive generations have suffered that no further evidence appears to them necessary. But if one can find a dozen (or even one) assured cases of tuberculosis without any evidence of the disease in the preceding generations all the so-called inherited cases can be explained by infection. The predisposition of man to tubercle, to the tænia solium, and certain other parasites is racial, just as other animals have their particular parasite. The explanation of parasitism is now undergoing solution. The current text-books of pathology give no support to the view of the inherited nature of tuberculosis.

---

[1] THE LANCET, June 17th, p. 1666.

I deprecated legislation or medical interference—*e.g.*, sterilisation—based on the *view that insanity is inherited.* For the present I will not respond to Dr. Campbell's challenge and decline to say whether I consider any forms of insanity are inherited. One of my purposes in criticising Dr. Reid's work was that I believed he had built up a [illegible] a few incorrect observations and [illegible] think it illegitimate *for scientists to warn legislators against, e.g.*, interfering with the licensing laws on such insufficient evidence.

Dr. Karl Pearson, in his interesting essay on Education prefaced to the "Encyclopædia Britannica," states that during the course of his investigations he received many foolish suggestions from all sources, but that the most unscientific and absurd came from medical men. This reproach will not be removed so long as we hold to formula instead of to facts, to loose expressions that sound well and mean nothing. A thrombus occurs in the jugular vein as part of a pathological condition; the reporter must needs remark: "The blocking of the venous channel was nature's effort to localise the inflammatory process." As well say the diseased patient was nature's effort to maintain the doctor. The College of Physicians might find employment for several censors confining themselves solely to medical literature.

I am, Sirs, yours faithfully,

June 23th, 1905. M. D. EDER.

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

To the Editors of THE LANCET.

SIRS,—I have read with considerable interest the various articles on "Medicine, its Practice and its Public Relations," which have appeared in *your columns since February last* and would like to make a few comments on the report of the *present state of medical education.* It seems to me this fifth year of the curriculum has been a "sore spot" ever since it was added, and the intention of the General Medical Council in lengthening the course from four to five years was undoubtedly that of enabling the student to devote his final year more entirely to clinical work. Why has this wise intention been frustrated? I think it is generally admitted that a serious waste of *time occurs during the first year* in taking the elementary subjects of chemistry, physics, and biology, whilst *later* the student also becomes hampered with the additional items which gradually continue to increase *in number.*

Now it occurs to me that the broad lines of reform necessary are these: (1) the subjects of chemistry, physics, and biology should be *passed previously* to commencing the curriculum; (2) the whole course of lectures and hospital appointments, including attendance on vaccination, fevers, ophthalmology, &c., should be completed in four years, including examinations, leaving only that of medicine and surgery to be accomplished at the end of the fifth year; and (3) the final year, or, at any rate, six or eight months of it, should be spent in compulsory pupilage to a registered general practitioner.

This latter suggestion may appear odd, but I have *formed* the opinion, and am confident of *many* who support it, that herein lies a problem of the utmost importance to the student, *the profession, and the* public. Undoubtedly the hospital system is a great advance on the old apprenticeship days, but we run the risk of serious *error in* excluding *altogether* this experience of general practice which formerly obtained. *I have heard the statement repeatedly* made by men, six months after qualifying and taking an assistancy, how much they regretted not having had *the same period in* actual practice prior to passing their final examination. Under existing conditions a man may even *possess his* diploma or degree without ever having been brought into contact with such a common malady as measles, and *of* course the knowledge of the management and routine of practice, to say nothing about the all-important *factor of tact and judgment* in dealing with the various phases of humanity, these things are a complete blank to him. And yet these are the men who when qualified seek assistantships in general practice and demand the usual salaries. They then discover that they have to learn *to apply* their knowledge in very different ways to those which were enjoyed in hospital life, surrounded by nurses and appliances *ready to* hand at any moment, and it is then only the man with skill and resourcefulness under awkward conditions who can hope to be successful.

It would be interesting to hear an expression of opinion from your readers on this matter. My point is that the curriculum of *five years should result in a complete* equipment of the student to manage at any rate a general practice and *resting exclusively on the* hospital training. I ask, Is it so?

I am, Sirs, yours faithfully,

Horbury, near Wakefield, June 27th, 1905. WALTER ASTEN.

THE TREATMENT OF RINGWORM OF THE SCALP BY THE X RAYS.

To the Editors of THE LANCET.

SIRS,—In reply to the letter of Mr. Winwood Smith in THE LANCET of July 1st, p. 49, I would say that, so far as the scalp in childhood is concerned, I have found practically no difference in the susceptibility of different individuals since I have been able accurately to measure the dosage by means of Sabouraud's pastilles. That there is, however, a difference in the susceptibility of different regions in the same individual there can, I think, be no doubt, and I should hesitate to apply to the face more than half the maximum dose for the scalp. It is said, too, that the largest dose which the skin can absorb without risk to its integrity is greater in the case of old people than in the middle-aged and greater in adults than in children. But upon *this point* I do not feel competent to give an opinion. Certainly an inflamed surface is much less tolerant than a normal skin and should receive a smaller dose.

I would explain the occurrence of radio-dermatitis in the *cases mentioned by Mr. Smith by the supposition* that, in spite of the apparently similar conditions, the output or the *quality of the x rays* was not the *same* in each instance; *the* same tube may emit a different amount and quality of rays during two *equal and consecutive periods of time, although* the primary current remains the same, for the tube may become heated by the passage of the current and so lowered in vacuum, thus allowing a greater amount of current to pass through it. Other points to be taken into consideration are: (1) the distance of the surface exposed from the anticathode of the tube, since with the same quality and quantity of rays coming from the tube the therapeutic activity varies inversely with the square of the distance; and (2) the *interval of time* between consecutive exposures, since if a second exposure takes place before the action of the first has passed off there will, of course, be a cumulative effect. I have no doubt that in the examples given by Mr. Smith the unequal results were due to the impossibility at present of insuring accurate dosage except by measurement of the rays as they leave the tube, which, so far as I know, can only be made by means of the pastilles of *Holzknecht* or of Sabouraud. The pastilles of Sabouraud and *Noiré may* be obtained *from* the maker, M. L. Drault, 57, Boulevard Montparnasse (VI^e^ Arrt.), Paris, *or* from Mr. Schall, New Cavendish-street, London, W.

I am, Sirs, yours faithfully,

Weymouth-street, W., July 1st, 1905. H. G. ADAMSON.

VINCENT'S ANGINA AND THE BACILLUS FUSIFORMIS.

To the Editors of THE LANCET.

SIRS,—In reference to the article on *the above subject*, which appeared in THE LANCET of May 13th, p. 1260, by Professor H. Vincent, the following case may be of interest. A native cavalry soldier came under my care last year for ulceration of the gums and loosening of the teeth. On the right side of the lower jaw the gum was swollen, pulpy, and tender, and was perforated in five or six places on the outer *aspect.* The first and second molars and both bicuspids were quite loose and might have been removed with the finger and the thumb. *On* pressure a considerable amount of fœtid pus welled up around the teeth and oozed out of the perforations *referred* to. The condition had *only* existed for a week or so and the chief complaint was the difficulty in masticating, the disagreeable taste in the mouth, and slight fever. The case was looked upon as one of Riggs's disease—pyorrhœa alveolaris—and treated energetically by local antiseptic applications and douching. A smear of the pus was taken and laid aside; the circulating blood was examined for malarial parasites with a negative result. About ten days afterwards and when the patient had recovered I had occasion to examine the smears of pus and was surprised to find a very unusual condition. One slide was stained by Leishman's method and one with methylene blue. The following organisms were present: (1) spirilla in very large numbers; (2) a short curved organism; (3) a diphtheroid short bacillus in masses; and (4) a long, curved, ribbon-shaped organism in small numbers.

To describe these in more detail: 1. The spirilla were very numerous and in some places matted so that as the organisms were frayed out from a common centre a "cat o' nine tails" appearance resulted. In size they varied from an average 14–18μ to extremes of 40μ and 10μ. The breadth was generally 1–2μ but certain individuals presented a thin ribbon-like form. There were two, three, or four curves in each spirillum. The continuity of some, especially the broader forms, was interrupted by a glancing spot or a definite chromatin-like body. Sometimes where many spirilla were collected several free, red (Leishman stain) round bodies were seen. I did not see any spirilla phagocytosed. 2. The short sickle-shaped body was generally about 7 or 8μ long by 2μ broad. The ends were rounded and the staining was not homogeneous. Almost invariably on careful focussing under a magnification of 1800 diameters chromatin-like particles could be made out and were sometimes visible as obvious red spore, or nuclear-like bodies. In the methylene-blue preparation some of these sickle bodies stained homogeneously, but in some evidence of division into a bacillary form was noted. 3. The diphtheroid bacillus was evidently quite independent of the other elements. In their arrangement these bacilli suggested the Klebs-Löffler bacilli in that they tended to lie in rows, squads, and palisades, but the resemblance stopped there. They were shorter and stained unevenly, so that in many cases it was just a question whether they were not diplo-bacilli. They showed marked metachromatism, or, at least, red particles, dots, and round bodies were seen lying in their protoplasm. They were nearly always aggregated into masses and were sometimes phagocytosed. 4. There were certain bodies, few in number, which looked like narrow curved ribbons. They were about as long as a spirillum but without indulations. They showed no trace of segmentation but, nevertheless, showed four or five well-marked blood-red rounded bodies lying at intervals in the pale blue protoplasm. Their size and general shape strongly suggested some relationship to the spirilla and especially to the broader forms mentioned under heading 1. They may have been spore-bearing bacilli but spores are not stained red by Leishman's stain after ten minutes' application. I do not know the relationship between metachromatism and the special phenomenon seen where nuclear matter reacts to Romanowsky's stain, but I feel sure that the appearance here noted is due to one or other of these causes.

It is interesting to note that the fusiform bacillus described and figured by Professor Vincent in the article above mentioned was not met with. The sickle-shaped body I describe could not have been identical, though it is possible it may have been an involution or degenerate form. In Dr. H. W. Bruce's article on this subject[1] I see, however, that he writes: "Shorter forms are seen (6–8 μ) occasionally curved and comma shaped. Very long badly staining bacilli are also sometimes present, and now and then a bacillus is seen which is greatly swollen in its centre, the expanded part not taking up the stain, whilst its edges are defined by a thin dark line." I think probably he is referring to the bodies which I have described under headings 2 and 4. In the descriptions of these two writers the fusiform bacillus was present in large numbers and the spirilla were looked upon as of less importance but in my case the spirilla were in enormous number and the other forms were few and far between. In my case, also, the pus was contaminated by the ordinary buccal organisms. In The Lancet of July 9th, 1904, p. 73, there is a note by my late teacher, Dr. A. E. Wright, on this subject in a short article called "Pathological Suggestions." I fully agree with him when he suggests that the fusiform bacillus is a stage in the life-history of a trypanosome. I believe that the spirillum itself, the fusiform bacillus, the sickle-shaped body, and the ribbon-like body I have described will all turn out to be different stages in the life of one parasite.

From the description of the fusiform bacillus in Professor Vincent's and in Dr. Bruce's paper it does not suggest the appearance of a true bacillus. Its length (as Dr. Wright points out) is against that; its vacuolation, which Professor Vincent lays stress on, and above all its behaviour to Romanowsky's stain, are highly suggestive of a protozoic origin. By this method chromatin in its densest form stains a brilliant blood red and so aggregations of nuclear material if young and active and the special chromatin structures in protozoa like the centrosome are always stained red. The spore bodies of protozoa, as those of bacilli, are both alike in being formed of highly concentrated nuclear material but are unlike in this respect that the bacillary spore is surrounded by a dense capsule which serves to protect it under its many vicissitudes in the ground or water but the spore body of animal parasites needs no such protection as its further stage is to be carried out in the body of another host. So the bacillary spore needs special staining methods to reveal it. If this is true, then, these red bodies in the protoplasm of the bacillus fusiformis cannot be spores of a bacillus and they are probably chromatin aggregations in the body of a trypanosome-like organism.

I have lately been carrying out some observations (as yet incomplete) on the changes undergone in trypanosomes under adverse conditions. The trypanosomes in the blood of an amphibious tortoise were watched in their course down the alimentary canal of a leech which had been allowed to suck the tortoise's blood. I found that the undulatory membrane and flagella at once disappear, that the body of the animal becomes longer, thinner, and more ribbon-shaped or else it becomes comma or crescentic shaped and seems to become quiescent and unaffected by the digestive fluids of the leech. The protoplasm becomes granular, the granules stain a blood-red by Romanowsky's method, and in the last stage I have yet seen three or four bright red spore-like bodies remain in the pale degenerate body of the trypanosome. I mention this because, comparing it with the forms seen in the pus from the case of pyorrhœa alveolaris, the resemblance is very suggestive. I regret that I was unable to make culture or inoculation experiments but the materials were not available and, moreover, until the appearance of Dr. Wright's paper the possibilities of the subject had not struck me. Dr. Wright calls attention to the occurrence of extreme anæmia with some cases of pyorrhœa alveolaris. This adds an additional interest and importance to the subject and looking further to Dr. W. Hunter's views on oral sepsis and pernicious anæmia it raises questions and possibilities which I have not the temerity to suggest.

I am, Sirs, yours faithfully,
F. Percival Mackie, F.R.C.S. Eng.,
Goona, Central India. Lieutenant, I.M.S.

---

[1] The Lancet, July 16th, 1904, p. 135.

TETANUS AND CHLORAL HYDRATE.

To the Editors of The Lancet.

Sirs,—I should like to express my thanks to Dr. J. M. Fortescue-Brickdale for the information given in his kindly letter in The Lancet of May 20th concerning the results obtained by French physicians in the treatment of tetanus with large hypodermic doses of chloral hydrate. The facts there stated clearly demonstrate the danger of overdosing tetanic patients with chloral hydrate but do not, I think, prove anything further. I quite realised this danger at the time of writing the article published in The Lancet of May 6th, and it was for this reason that I suggested "the advisability of commencing the treatment of an adult case of tetanus by doses of about 30 or 40 grains of chloral hydrate and steadily increasing this to a drachm or more until the desired effect was produced, repeating the dose when the spasms recurred, and gradually reducing the quantity as the spasms became less violent in character." If this method of administering the drug were tried the danger of overdosing would be reduced to a minimum. In the cases quoted by Dr. Fortescue-Brickdale, very large doses of chloral hydrate were administered either intravenously or subcutaneously and deep anæsthesia was produced with fatal results in many cases; these cases are consequently not quite on a par with the case I published, in which the drug was administered per os and per anum and only a very slight degree of anæsthesia was produced. The proposition I am anxious to see proved or disproved is that the poisons of tetanus and chloral hydrate are antidotal. In the early days of administering mercury in the treatment of syphilis, overdoses of the drug possibly accounted for nearly as many deaths as the disease itself. To-day we are wiser; our faith in the antidotal power of mercury is, however, an established fact. If we can establish a like relation between chloral hydrate and tetanus another useful weapon will be added to our equipment.

I am, Sirs, yours faithfully,
JOHN MABERLY, M.R.C.S. Eng., L.R.C.P. Lond.
Woodstock, Cape Colony, June 12th, 1905.

PROLONGED ANÆSTHESIA BY CHLORIDE OF ETHYL IN OPERATIONS ON THE NOSE AND THROAT.

To the Editors of THE LANCET.

SIRS,—I have for some time past been working out a method of maintaining anæsthesia in short operations on the nose and throat by means of the vapour of ethyl chloride administered through a tube. By short operations I mean those lasting a little longer than two minutes which is about the limit of available anæsthesia after an ordinary dose of ethyl chloride administered in the usual way. Last winter I brought the results of my first 20 cases before the Society of Anæsthetists. I have now completed nearly 100 cases by the method which I am about to describe with almost universal success, the partial failures I have had being in subjects, not infrequently met with, who do not take ethyl chloride well in any circumstances. My experience has been that where anæsthesia is easily induced by the ordinary method it is easily maintained by means of my apparatus and *vice versâ*.

In order to have a good supply of vapour it was necessary to have a fair bulk of ethyl chloride put up in a suitable chamber, absolutely gas tight, with a suitable tap for the delivery of the vapour through a tube to the patient's mouth or nose. Mr. Paxton, of 93, Dyer's Hall-road, Leytonstone, has made me some in various patterns and sizes and assisted me with much valuable advice as to details. The one which I have finally adopted is a metallic cylinder, holding about 250 grammes, with a screw-down stopper on top which on being partially unscrewed admits the vapour to a tap on its side, whence it passes along a tube to a suitable gag; I use either a Probyn-Williams or a Wingrave with a short metal tube fixed at right angles to the upper blade. The gag must *always* be inserted before commencing this anæsthetic, otherwise there will be difficulty in opening the jaw. Having done this five cubic centimetres of ethyl chloride are administered in the usual way with the ordinary closed apparatus. I generally allow from one to two minutes for the induction getting the patient deeply under, the length of time depending very much on the age and strength of the individual. As soon as the mask is removed the operation commences and I turn on the taps and a little vapour passes down the tube. This would very soon stop owing to the rapid cooling produced by evaporation, but I have at hand a porringer of hot water in which I put the chamber from time to time causing a rapid ebullition. I economise vapour by pinching the tube during expiration with the hand that steadies the gag, and at times for several breaths the tap is turned off altogether lest the anæsthesia get too deep. I generally aim at having a slight corneal reflex, a moderate pupil, and deep regular, but not stertorous, breathing. In this way I have maintained a good anæsthesia in cases lasting from three to 20 minutes at an average expenditure of less than five cubic centimetres of ethyl chloride per minute of available anæsthesia. Except for some special reason I should not advocate the use of this method in operations lasting over ten minutes on account of the expense. In considering the advantages one has to compare with other methods. The only two I know of are gas through a tube or chloroform in a Junker. Of the former I have no practical experience but I am inclined to think that the results would be less certain. The cost would certainly be greater and the weight of cylinders to be carried about is a disadvantage. My ethyl chloride cylinder takes up but little room and when full only weighs 21½ ounces, the contents being sufficient for 50 minutes' anæsthesia or, say, ten cases of five minutes each.

The advantages of this method over chloroform are: (1) Rapidity—a short operation can be finished in less time than it takes to get the patient under chloroform; (2) safety—especially in the sitting position; (3) slighter after-effects; and (4) greater freedom for the anæsthetist to assist, no hand being required to work a bellows There are many minor details into which I might enter but I fear I have already trespassed too far on your space. I will only add one word of warning in conclusion. The ethyl chloride used in charging should be guaranteed made from pure alcohol and free from impurities, otherwise the taps would soon become corroded and ruined. I speak from experience.

I am, Sirs, yours faithfully,
G. A. H. BARTON,
Westbourne-park-road, W. Anæsthetist to Throat Hospital, &c.

LUNACY ACTS AMENDMENT BILL (LONDON) (NO. 2).

To the Editors of THE LANCET.

SIRS,—Since the writing of your very able and exhaustive leading article this Bill has been dropped. You have dealt so completely with the subject that there is very little to add.

That very good work is being done by the metropolitan infirmaries is evidenced by the fact that in 1904 out of a total of 7654 admissions of "alleged lunatics" only 3716 were sent to asylums and 3155 were discharged cured within the period of 14 days, which represents the limit of legal detention in an infirmary or workhouse, and if this period of detention could be extended for another 14 or 28 days a sensible addition would be made to the list of cures. To your formidable array of objections may I point out the hardship which would be inflicted upon the friends of the patient, caused by the necessity for their attendance at the receiving house which must in many cases be some miles from their homes and also that a check upon abuse of enormous value would be abolished. The proposal of the London County Council revolutionised the intention of all previous lunacy legislation which has hitherto regarded it as an essential point that the authority which primarily receives and certifies the cases should not be the same body which has the power of indefinite detention.

Most boards of guardians have during recent years recognised their responsibility and have at considerable expense erected efficient mental wards and are naturally very wroth that their constituents should be called upon to pay an extravagant sum for the realisation of an idea. The party whip has, however, been very vigorously cracked over this matter and many otherwise level-headed administrators have been compelled to "toe the line" sorely against their convictions. The knowledge that we have your support will materially strengthen the position of those who have consistently opposed this proposition since its inception in 1897. I inclose a copy of the report upon this matter, adopted at a recent conference of the medical officers of metropolitan infirmaries and workhouses, called specially to consider this scheme and which unanimously condemned it.

I am, Sirs, yours faithfully,
F. S. TOOGOOD, M.D. Lond.,
Honorary Secretary to the Conference of Metropolitan Poor-law Medical Officers.
Lewisham Infirmary, July 3rd, 1905.

THE RECENT OUTBREAK OF TYPHOID FEVER AT LINCOLN.

To the Editors of THE LANCET.

SIRS,—After the appearance in THE LANCET of July 1st, p. 22, of a "Note on the Recent Outbreak of Typhoid Fever at Lincoln" by Mr. E. Cecil Clements the following additional observations relating to the same outbreak may be of interest. They are based on 138 cases of typhoid fever which occurred in the practice of my friend, Dr. Andrew Burgess of Lincoln, whom I was assisting at the time. In almost every case the skin of the palms of the hands and the soles of the feet was of an intense yellow colour, deepest on the thicker parts of the skin. In some of the severer cases the colouration extended to the skin on the tops of the toes. The hands were affected first—generally at the end of the second week—and the feet soon after. The coloured epithelium next cracked and peeled off in big flakes. One girl shed an abundant crop of warts. The hands were the first to resume their normal appearance. In some cases the skin on the soles of the feet was yellow and peeling freely two months after the onset of the fever. A few patients complained of burning pains in the soles of their feet. The peculiar green stools mentioned by Professor J. Dreschfeld in Allbutt's "System of Medicine" were noticed towards the end of a relapse in two cases. Hæmaturia was noticed in two cases and nephritis with retention of urine and œdema of the face in one case. A case of the apyrexial form of typhoid fever was met with in a boy aged ten years. His temperature was normal throughout with the exception of a single rise on one occasion to 101·6° F. and his pulse was slow—from 56 to 60 per minute. All the other symptoms associated with typhoid fever were present.

Towards the end of the outbreak measles was very prevalent and three cases were seen where typhoid fever and measles were running concurrently. The first case was that of a boy, aged five years, who had a typhoid rash on Feb. 24th and a measles rash on the 26th. He also had hæmorrhage from the bowel on March 3rd and 4th. The second case was a boy, aged six years, who had a typhoid rash on March 19th and a measles rash on the 26th. The third case was a boy, aged six years, who had been troubled with a tapeworm for three and a half years. The typhoid rash appeared on Feb. 17th and on March 21st the measles rash came out. He had troublesome diarrhœa, passed blood on many occasions, and now and them parted with segments of the tapeworm. Two other children in the same house were down with measles at the same time. The symptoms of both diseases were not modified in any way in any of the cases.

I am, Sirs, yours faithfully,

J. F. HODGSON,

Assistant Medical Officer of Health, Halifax.

July 3rd, 1905.

HYDROCHLORIC ACID IN THE GASTRIC CONTENTS AND CANCER.

To the Editors of THE LANCET.

SIRS,—The paper read by Professor B. Moore at the Royal Society and published in THE LANCET of April 29th, p. 1120, on the absence or marked diminution of free hydrochloric acid in the gastric secretion in cases of cancer other than gastric seemed to offer an easy method for solving the difficulty of diagnosing between malignant and benignant new formations. I have recently had opportunity of testing the gastric contents in eight cases of cancer where implication of the stomach could be excluded. In four there was absence of free hydrochloric acid in the fluid drawn off from the stomach after a test meal. In the other four there was a very marked positive reaction. All the eight cases have been examined microscopically. I was rather disappointed at this result as I had hoped that at last an easy method for distinguishing between innocent and malignant growths had been devised. This, however, does not appear to be the case, for although the test (i.e., phloroglucin and vanillin) was applied only qualitatively, yet it is sufficiently sensitive to allow the observer to obtain a fair estimate of the quantity of free acid present. To apply it quantitatively is at present outside the region of ordinary practical clinics. All the eight patients were treated alike but the fluid drawn off was very dissimilar and the difference in quality may possibly afford a clue to the discrepancy in the results, for in those without acid it was watery and had almost no solid, while in those which gave a marked reaction it was semi-fluid and contained much solid matter.

I am, Sirs, yours faithfully.

Westminster Hospital, S.W., July 3rd, 1905. R. G. HEBB.

RUSSIA'S SECOND CONGRESS ON PSYCHIATRICS: 18 YEARS' INTERVAL.—The Second Congress of Russian Psychiatrists will be held in Kieff from Sept. 17th to 24th next. One of the psychiatric societies had expressed the opinion to the organising committee that in view of the difficult situation in which Russia finds herself just now the holding of the congress seemed inopportune. The organising committee nevertheless explained the extreme necessity and urgency, as to time, of the congress, the chief cause being "the imperative call for attention by the unfortunate psychiatric patients in the hospitals, the last congress on the subject having taken place 18 years ago. Besides which it was necessary to think of, and to consult on, those new highly complicated cases resulting from the present serious war and the tension undergone by the people in the great upturn in their social life." The report, says the *Novoe Vremya*, will be printed at the public cost.

DAVOS-PLATZ.

LAWS AND REGULATIONS IN REGARD TO TUBERCULOUS PATIENTS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

I.

DAVOS-PLATZ is so well known as a station for the treatment of pulmonary tuberculosis that it is not necessary to attempt a general description of the place or a recapitulation of its history. Suffice it to say that Davos is a valley which, though situated at 5350 feet above the sea, is nevertheless surrounded by high mountain scenery, some of the mountains in the immediate neighbourhood reaching an altitude of more than 10,000 feet. The result of this situation is an average temperature similar to that of St. Petersburg —namely, 36·5° F. From the middle of November till the end of April the place is deeply covered with snow, but, on the other hand, there are powerful sunshine, clear, pure, strong light, reduced atmospheric pressure, no fog, few clouds, very little moisture or rain, and shelter from the colder winds. It was not, however, till 1865 that two invalids suffering from pulmonary tuberculosis ventured to pass the winter there. The result was so favourable that others followed their example and thus the sparsely inhabited mountain valley became the present fashionable winter station. The influx of visitors increased so rapidly that the simple peasants who lived in these mountains did not know what to do with all these strangers. Davos-Platz was but an official centre where the church, the municipal building or Rathhaus, the post-office, and a few houses clustered together. Most of the natives live in wooden cottages built in the midst of their fields and dotted about over the vast commune. This is one of the reasons why the statistics in regard to the immunity from infection among the natives are of but little importance. It has been said that if tuberculosis is infectious then there would be an increase in the number of cases among the native population. A considerable effort has been made to obtain statistical information on this point and such observations might be of universal interest. The statistics obtained are not, however, absolutely trustworthy. There has been no attempt to manipulate the figures. What has been done has been honestly done. But in these sparsely populated mountainous districts skilled medical attendance is not easy to obtain and sometimes the only evidence as to the cause of death was that given by friends or relatives. Nevertheless, it is fairly evident that the native population has not been infected by the advent of an enormous number of visitors. The death-rate from tuberculosis among the natives has been below 1 per 1000 per annum. On the other hand, the statistics are based on the number of inhabitants of the whole commune which includes not only Davos-Platz and Davos-Dorf but many miles of surrounding pasture land and mountain. During the 25 years 1876 to 1900 the average native population numbered 1315 and among them there were in that time 36 or 38 deaths from tuberculosis according to whether two doubtful cases are included or not. This is equal to an annual death-rate from tuberculosis of 0·91 or 0·97 per 1000. Only 4·64, or 4·94, per cent. of the total deaths were due to tuberculosis. On the other hand, another set of statistics gives the numbers showing the immense increase of population and of visitors. These amounted to 6830 in 1886, to 10,167 in 1890, and to 15,800 in 1900. In addition to this and in accordance with the census of Dec. 31st, 1900, there were in the commune of Davos 1387 burgesses—that is, peasant proprietors or natives; 3086 other Swiss inhabitants, and 3861 foreigners who had settled in the town Of these there were 266 Swiss and 2268 foreigners notified as having taken up their residence in the commune for at least three months and probably for a longer time. All who did not remain three months at Davos were counted among the 15,800 visitors.

The problem presented by Davos is that of a valley high up in the mountains with a sparse and scattered native population suddenly invaded by a large number of patients, a smaller number of pleasure-seekers, and then again a large number of hotel-keepers and their servants, of shopkeepers and their assistants. The sturdy peasants of Davos might have known what to do to resist a hostile attack from over the Austrian border which is not far away; but this fashionable invasion of friendly people willing to disburse what seemed fabulous sums of money for luxuries unknown among these hardy mountaineers, that was a contingency for which they were in no wise prepared. In vain these peasants came down from their mountains, gathered together in their antique Rathhaus and debated as to what had best be done. The facts of the case grew altogether beyond the experience of their oldest and wisest municipal councillors. So the new-comers, the strangers who had arrived to settle and to trade in the new winter station, took the matter in their own hands. In August, 1871, they constituted a committee for the embellishment of the station. In four years this developed into the Curverein which is practically the local administrative body. On the ground that this committee was organising facilities for the treatment "cure" and for the enjoyment of the visitors it levied a tax of 2½*d.* per day or £1 per annum on visitors. Then it has undertaken various public works such as the water-supply, the drainage, the building of roads, the providing of seats on mountain paths, and vast installations for the sports—the skating, the toboggan races, &c.—that attract so many people other than patients.

In all this there were not only the ordinary public health considerations that arise in all towns but the special risks resulting from the fact that the majority of people who visit Davos-Platz are suffering from tuberculosis. At first, of course, nothing was done; but as the infectious nature of tuberculosis became better known the necessity of taking measures to minimise the danger also became more and more obvious. Disinfection and the prevention of expectoration in public were the two most urgent special measures needed. Nevertheless they were opposed at first even by some of the local practitioners. Now, however, the existing new laws and regulations may be considered as quite in harmony with what is generally conceived to be desirable in such circumstances. What then has experience proved to be necessary in a great centre for the treatment of tuberculosis? This is a matter of practical importance and worth while examining in detail. Considering the large number of invalids and the importance of rest to these sufferers, it was obvious that at night there must be no noise. Therefore there is a series of by-laws against noisy games, such as skittles, *morra*, and against innkeepers or others who allow noisy assemblages or games on their premises at night. Of course, exceptions are made for certain fête days, for weddings, &c.; still, and, as a rule, not a sound is to be heard at night and this is undoubtedly a great advantage for the patients. The hawking of goods in the streets is forbidden as also are the bringing and the sale of cattle in the town, and every driver who uselessly cracks his whip is fined 4*s.* All the fines paid for breaking any of these rules go to the funds of the Curverein.

Having thus taken measures to prevent the patients being disturbed by unpleasant noises the next thing was to see that they are not inconvenienced by unwholesome odours. All cesspits or other receptacles for stagnant and foul waters are forbidden. They must be drained directly into the sewers. No deposit of refuse, such as rags, is allowed within 100 feet of a house or a public road. No accumulation of stable manure except in a closed receptacle is sanctioned within the town, nor is it allowed to beat carpets or bedding in the public streets. All private yards must be kept scrupulously clean and no one is permitted to burn refuse or any object that may cause smoke or an unpleasant odour. Coming to the question of disinfection this is a matter of such importance in all countries and on which so much doubt still prevails that it may be useful to give the actual text of the law:—

Law of July 2nd, 1886, on epidemics which
[illegible]nsidering the cantonal regulations enacted
[illegible]w; the following measures will be enforced
at the station of Davos on and after June 1st, 1901:—

Article 1.—All rooms occupied by tuberculous persons, as also all objects contained therein, such as beds, clothes, linen, bedding, &c., must be thoroughly cleaned and disinfected before they are used by other persons [illegible] rules
A [illegible] l men
dra [illegible] all be
of [illegible]
pe[illegible] hem-

Th[illegible] apparatus and the substances selves proceed to disinfect with the [illegible] under the surveillance of agents [illegible]erein.

[illegible] ust inform the Curverein within 24 hours when a patient leaves. All such rooms must be disinfected unless a medical practitioner gives a written dispensation. Such disinfection need not be applied in the case of rooms occupied by ordinary travellers and commercial travellers.

Article 4.—All patients suffering from chest disease are under the obligation of carrying on their person a pocket spittoon. They are forbidden to expectorate on the [illegible]
of hardware, of glass, or of an [illegible]
every day and should contain [illegible]

Article 5.—It is not admissible that persons suffering from chest diseases should expectorate on the causeway, the road, paths, &c.

Article 6.—Persons who are found by a medical practitioner to be suffering from a contagious disease other than tuberculosis and enumerated by the law on public health, shall be taken to the isolation house, unless the district medical officer shall declare this is not necessary.

Article 7.—The prescriptions of the Swiss Federal law of July 2nd, 1886, and the cantonal rules for the execution of this law, and the instructions given by the medical officer of the district apply to the disinfection of the rooms, beds, clothes, linen, bedding, and to the means of transport employed by the patients as enumerated in Article 6. The Curverein carries out this disinfection.

The following article (No. 8) at first stipulated that any contravention of the above might be punished by a fine not exceeding £2. But Article 5 was omitted. Now this is no longer the case and any patient who expectorates in the street is liable to be fined £2. It will be noticed that at first it was said that it was "not admissible" that a tuberculous patient should expectorate on the ground. This was the period of moral suasion; and then, as public opinion became educated to the point, the public authorities ventured by a by-law of December, 1904, to include Article 5 with the other clauses and now its infraction entails a fine of from 2 to 50 francs. On this subject I ventured to ask the director of the Curverein what he would do if he saw anyone expectorate in the street. The reply was that he would go up and ask the delinquent for his name and address. If he proved to be a stranger and expressed his ignorance of the law and his regret a few words of warning would be considered sufficient. But if it was an old offender or he refused his name and address then, the director said, he would follow him till he met a policeman and then he would give him in charge.

In regard to disinfection, the rule is that all rooms let out must bear a number. Thus visitors are registered on arrival, with the number of their rooms. When they leave the authorities are informed of the number of the room that has been vacated. By telephone with the Curverein an appointment is at once made and the hour for the disinfection is settled. At that time an inspector, who is selected by the Curverein and whose position is legally confirmed by the municipality, presents himself. This functionary alone has the right to close the room and to reopen it. No one has the right to enter the room during the process of disinfection. When but one room is disinfected the charge made by the Curverein is 7 francs (5*s.* 7*d.*) but if it is a suite of rooms then the charge is 4*s.* per room. Trioxymethylene is evaporated on a spirit lamp and the process requires about seven hours. All hotel keepers, and lodging-house keepers or the managers of sanatoriums have to notify the Curverein not only when a patient leaves but even if he merely changes from one room to another within the same hotel or building. In that case the room formerly occupied has to be disinfected. At the end of the year the cost of the numerous disinfections which have been carried out is submitted to the municipality, together with the receipts, and then the municipality decides whether the charges are sufficient or insufficient; in a word, whether any alteration in the tariff is necessary. From this it will be seen that not only is it illegal to allow a healthy person to sleep in a room which has been previously occupied by a tuberculous patient but even patients who are themselves tuberculous must not sleep in a room where the previous occupant suffered from the same disease. In every case the room must first be disinfected. So that really a traveller or visitor is safer at Davos-Platz than he would be in London, Paris, and most other towns where no such precautions are enforced. Then there are also hotels and boarding-houses at Davos-Platz and Davos-Dorf which make it a point not to accept invalids as lodgers. If any patient accidentally gains admittance he is at once sent away and his room is disinfected. Consequently a traveller would incur less risk at Davos, where the majority of the visitors are patients but where every precaution is taken, than in an ordinary town where there are comparatively few cases of tuberculosis but where no precautions whatever are enforced. It may also be noted that private slaughter-houses are abolished and that no meat can be sold at Davos which does not bear the stamp of the meat inspectors who are on duty at the public slaughter-house. The trade in milk is likewise subjected to various regulations and methods of surveillance to prevent its contamination and adulteration. Thus the authorities have taken measures to secure for the population, and especially for the patients, good wholesome food.

In visiting the sanatoriums of Nordrach, of Davos-Platz, and other places, my object was two-fold. First to accumulate evidence and information which should be of practical service in showing how popular sanatoriums should be established and managed in England; and secondly, to set forth the deficiencies of the so-called sanatoriums established by the late Mr. J. J. Jones at Sandgate and the necessity of legislative interference for their abolition. Therefore, and in regard to the latter point, as the late Mr. J. J. Jones advertised that at Sandgate the treatment given was similar to that generally practised at Davos-Platz, it is quite fair to ask whether when the late Mr. J. J. Jones was a member of the Sandgate district council he attempted to obtain the enactment of by-laws for Sandgate at all similar to those described above and applied at Davos-Platz. Was any effort made to *prevent* the cracking of whips and such noises as might disturb the patients at night? There is this similitude between Davos-Platz and Sandgate, that in both instances there are patients in the centre of the town, though at Davos-Platz all the popular sanatoriums are well away from the main road and the centre. In regard to disinfection, Mr. A. R. Bowles, surveyor and sanitary inspector of the Sandgate district, testified before the House of Lords Select Committee on the Sandgate Sanitary Powers Bill that the Jones's home, known as Grosvenor House, had been used as a convalescent home for phthisical patients and then for ordinary boarders. The local authority had not been informed of these changes nor was there anything to show that the place had been disinfected. As sanitary inspector he had never been asked to disinfect when changes were made. The medical officer of health of Sandgate, Dr. C. E. Perry, also bore witness that he had never been called upon to disinfect any of the Jones's homes. It was, however, stated that at least on one or two occasions Mr. Jones had burnt some sulphur in the rooms, notably of Ontario House. Mr. A. J. Gore, who is now in charge of these houses, declared that after the tuberculous patients had been removed from Ontario House and before ordinary convalescent patients were admitted to this home he himself saw the place thoroughly disinfected with formalin and sulphur. On the other hand, Dr. H. Scurfield, medical officer of health of Sheffield and professor of public health at the University College of Sheffield, testified that a medical man did not necessarily know how to disinfect a room. This is an obvious but an important point. It does not form part of ordinary medical education to teach a medical student how to cut long slips of paper or cotton-wool and to render a door or a window airtight, nor is a medical practitioner necessarily an adept at stopping up a chimney. He may know theoretically when it is indispensable to disinfect but the various processes of disinfection are matters of handicraft that form part of the education of an inspector of nuisances and other municipal functionaries. Therefore no disinfection can be counted as satisfactory unless, as insisted upon at Davos-Platz and many other places, it is carried on under the control of the public sanitary authority. Nothing of the sort was done at Sandgate and the contrast between Sandgate and Davos-Platz in this respect is most detrimental to the former town. Finally, it may be observed that before Sandgate can be compared with Davos-Platz a public slaughter-house must be constructed and more rigorous methods of controlling the food-supply introduced.

(To be continued.)

CHOLERA, PLAGUE, AND OTHER DISEASES IN THE NEAR EAST.

(FROM THE BRITISH DELEGATE ON THE OTTOMAN BOARD OF HEALTH.)

THE Turkish empire continues to be quite free from cholera. It is less certain whether Persia is equally so. Reports from Tehran, dated March 29th and April 5th and 12th respectively, stated that the sanitary condition of that country was satisfactory and that no case of cholera had been observed there since Feb. 26th. But the report of April 19th asserted that, in spite of official assurances, there were rumours that cholera was still prevalent at Meshed and at other places in the Khorassan province. On May 8th it was reported that sporadic cases of the disease were occurring in Tehran itself. The latest news, on the other hand, is to the general effect that the public health conditions of the country are "satisfactory", but on June 5th it was reported that some cases of "choleriform diarrhœa" had been observed at Hamadan.

Single cases of cholera are officially reported to have occurred on Russian territory at Askhabad on April 19th (May 2nd) and at Tsaritsyn on the Volga on April 21st (May 4th), and two suspicious cases were reported on May 15th from the Bogorodsk district of the Moscow government. No later news has been received and the presumption consequently is that no cases have been observed since.

The outbreak of plague at Aden has come to an end. During the week ending May 20th there were neither cases nor deaths from the disease. During the following week two cases and no deaths were reported. The last new case was observed on May 24th.

A sharp outbreak of plague has recently occurred at Bahrein, in the Persian Gulf. The date of the first case is not known but it was probably about May 10th. Up to the 20th of that month 20 deaths from the disease had been reported. Five days' quarantine was consequently imposed in Turkey upon arrivals from that island. News has since been received that the outbreak is declining. On the 19th of the same month two cases of plague were observed on a Persian Government boat, the *Persepolis*, which had arrived at Bushire from Bombay.

No further cases of cerebro-spinal fever have been reported in this city. In Russia, on the other hand, according to official news received here, this disease has been showing much activity recently. At the beginning of May some doubtful cases were reported from Rostof on Don and Kremenchug. Down to the end of April (old style) the number of reported cases in all Russia had been as follows: In January, 4; in February, 7; in March, 27; and in April, 15. Among the places in which the disease had been observed were the towns of Stavropol (in the Caucasus), Rostof on Don, Yaroslavl on the Upper Volga, and Lublin in Polish Russia, and the districts of Bendinsk in the Piotrkow government, and of Kuopio and Nyland in Finland. In addition three cases and one death were reported from Taganrog in May; five deaths also occurred in the Polish government of Radom, and (in April) two cases in the Elisavetpol government, nine in that of Kuopio, two in that of Viborg, and single cases in each of the Finnish governments of Nyland, Tavasthus, Abo, Bjorneborg, and Wasa.

Constantinople, June 29th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Medical Officers of Health and Motoring.

THE north-western branch of the Incorporated Society of Medical Officers of Health held its annual meeting at Lancaster on July 1st. A paper on the Public Health Aspect of Motoring was read by Mr. Herbert Jones who spoke approvingly of its indirect benefits, such as the great increase of housing space in large towns that would result from the removal from their centres of "all horses and carriages and carts and wagons," besides the advantage of doing away with a huge mass of offensive material. The horse must be stabled near its work but the motor might be kept ten miles away. The public health would be benefited by the cessation of "the wholesale dissemination of organic material contained in horse manure," which was shown by Professor S. Delépine to be the cause of extensive outbreaks of diarrhœa in Manchester. Mr. E. Sergeant, the medical officer to the Lancashire county council, thought the disadvantages greater than the benefits. The dust was a distinct danger and until roads were made fit for motoring, not only in regard to their surfaces but their width, he was of opinion that it was dangerous to health. Mr. J. J. Weave (Southport) said that the dust problem was largely due to the make of cars and might be left to engineers and road-makers. Dr. Meredith Young (Stockport) spoke of the great waste of water necessary to keep down dust on roads and streets and said that motors would compel engineers to consider the best way of preventing dust. Mr. J. Settle (Barrow) was not thankful for the coming of motor-cars but feared they had come to stay. Mr. A. W. Martin (Gorton) spoke of the indirect benefits that would accrue to agriculture and said that if dust were got rid of, as it would have to be, the death-rate would be lowered and a diminishing birth-rate need not be feared. The President, Dr. J. F. J. Sykes, said that motors would ultimately lead to the improvement of the roads which would be a good thing. Motors did not make dust, they only raised it. In all this discussion nothing seems to have been said of the direct danger to life caused by reckless or unskilful driving. but the newspapers bear almost daily testimony to the reality of this danger and in too many instances to cowardly attempts by the motorists to get away without caring to learn the injury that they have done. Those who often experience the sickening smell accompanying the clouds of dust raised in dry weather on country roads, clouds frequently dense enough to hide the car and its occupants in a few yards, have, no doubt, borne without taking action a nuisance which is declared by this society of health officers to be dangerous to health and therefore to life. Hence it is clearly their duty to take such action as may be necessary to make the roads and streets a little safer than they are at present from danger to life and limb and freer also from the dust dangers which they unite in condemning. But the subject bears sometimes a slightly comic aspect. A case that occurred on the same day as the meeting at Lancaster —July 1st—at Kendal shows that a medical officer of health may differ in opinion from some of his brethren and take steps, as no doubt he ought to do, to guard himself against the dangers of the road. A man was summoned for failing to stop his motor-car when requested to do so by the driver of a horse and trap. Mr. R. M. Craven stated that when driving along one of the Kendal roads he saw a motor-car approach. When within 80 yards of it, being afraid that his pony would shy, he put up his hand and also a flag as a signal for the driver to stop. "Why don't you stop?" he asked the driver, who made no reply. He admitted having written to a newspaper saying: "I am a horse-driver and enforce my rights on the highway. I have a red bunting flag and when I hear a motor-car coming I raise my hand and my flag. If the motor-car driver gives me my side of the road and slows down to six or eight miles an hour I lower my flag and allow him to come on. If he does not I keep my flag aloft and stop him dead until I drive my pony past him." The defendant in his evidence said that when he met Mr. Craven "he pulled up dead slow until he reached him." To show how our own conduct, eminently sane as we think it, may strike one looking at it from another standpoint the defendant said that when passing he remarked to his brother that "the man must be mad." He was "completely dumbfounded by the red flag," so that it is evidently a valuable weapon with which to encounter motorists. The magistrates dismissed the case, the defendant paying the costs, *22s. 6d.* It seems a little hard that motorists should almost monopolise the high roads, to the maintenance of which they contribute so little, and if the roads are to be widened and made dustless the cost should fall on those who make the change necessary and not on the long-suffering local ratepayers.

Bravery.

In THE LANCET of April 1st a brief narrative was given of the brave doings of the boys at the school for the deaf and dumb at Preston when a fire broke out. It is gratifying to learn that silver medals are to be given to two of them, Nicholas J. Dalton and John Jackson. The fire was discovered in the early morning and "the two lads climbed down a waterspout from the dormitory windows, summoned assistance, and helped to bring ladders by which their comrades escaped from the dormitories." At Preston, by the way, a lad, aged 12 years, while bathing in the Ribble recently got out of his depth and was saved from drowning by a man named Albert Edward Lowe who had previously saved eight lives.

Smoke and the Magistrates.

Some places seem to delight in the manufacture of smoke and to be as proud of it as if it were their best paying product. At Sheffield on June 22nd an Attercliffe firm answered a summons which alleged that they had disobeyed an order to abate a smoke nuisance, "but the case was not heard because the magistrates on the bench, themselves cutlery manufacturers, declined to adjudicate." The chairman, Mr. J. E. Beal, said: "You had better take it to the other court; you will not get any sympathy from me," and he declined to hear it. The summons was then taken to the other court and there, also, the chairman, Mr. G. F. Lockwood, declined to hear it. On the face of it this "passive resistance" by the magistrates does not look creditable but it may be that tenderness of conscience sometimes prevents sinners from rebuking sin.

Tests of Sobriety.

Mr. E. A. Humphreys of Northenden, surgeon to the police, recently described at the Stockport police court his test for drunkenness as applied to three men accused of being drunk on licensed premises. He made them shut their eyes and walk backwards, and he said that few men could do it when sober and if they succeeded they were certainly not drunk. They had also to write their names with a quill pen, to walk along a straight line, and to stand still with their heels together. He accepted the definition in Murray's dictionary that a drunken man was one who had ". taken intoxicating liquor to an extent affecting steady self-control" and described the symptoms as "staggering when walking, incoherent speaking, and lack of reasoning power." There is no doubt that the tests named are applicable to those in the condition described, but they do not cover those cases of more complete narcosis where the diagnosis between drunkenness and brain mischief is not self-evident.

July 4th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The Somerset County Council and a County Medical Officer of Health.

THE question of the appointment of a county medical officer of health of Somerset has been often discussed at the meetings of the Somerset county council. At a meeting held at Wells three months ago the sanitary committee obtained the sanction of the council to a proposal to appoint a medical officer of health at a yearly salary of £150, travelling and other expenses being estimated at another £100. Applications for the appointment were duly advertised for and 30 gentlemen applied for the post. Four candidates were selected and attended the meeting of the county council held at Taunton on June 27th. Unfortunately for the candidates a member moved that the resolution passed at the previous meeting providing for the appointment of a county medical officer of health should be rescinded and this was carried by a majority of one. The chairman expressed regret that the candidates had been asked to attend unnecessarily and assured them that their travelling expenses would be paid. Following upon the decision the chairman of the sanitary committee resigned his connexion with the committee and suggested as his successor the mover of the rescission of the previous resolution.

The Water-supply of Taunton.

A new storage reservoir, capable of holding 120,000,000 gallons, in connexion with the Taunton water-supply was formally opened by the Mayor on June 30th. The reservoir is situated at Luxhay, on the Blackdown Hills, eight miles from Taunton. It will have a water area of 17 acres when filled, with a depth of water of 57 feet. The cost of the undertaking has been about £26,000.

The Royal Hamadryad Seamen's Hospital, Cardiff.

The old *Hamadryad* ship has done good service during the past 40 years as a hospital for sick and injured sailors who land at the Port of Cardiff but it has been realised for some years that a building with more modern requirements ought to be provided and in 1897 it was decided to commemorate the diamond jubilee of the late Queen Victoria by establishing such an institution. The late Marquis of Bute associated himself with the project in the heartiest manner. He gave the principal portion of the site and at once subscribed £10,000 towards the building fund. After his death, which occurred shortly afterwards, it was found that his trustees were empowered to give further sums up to a total of £30,000 if they were required, so that it has been possible to provide a building well equipped in every respect. There are three main wards each containing 16 beds, and smaller wards bringing up the total accommodation in the hospital to 60 beds.

The walls are of impervious parian cement with rounded corners and the floors are of terrazzo. The architect, Mr. E. W. M. Corbett, took some pains to ascertain from the principal officers of existing hospitals which was the best material of which to form the ward floors and finally decided in favour of terrazzo. The ventilation of the wards is provided for by the so-called "natural method" by means of floor level inlets and outlets in the flues. The incoming air can be warmed if necessary by radiators. The warming is by low-pressure hot-water pipes. The entire building is lighted by electricity. Adjoining the hospital proper is a detached residence for the medical superintendent. Three of the beds have been endowed but for the maintenance of the hospital the managers rely principally upon a voluntary tax which the shipowners levy upon themselves. The foundation-stone of the institution was laid in 1902 by the Marquis of Bute when he came of age and was formally opened by him on June 30th last.

The West Cornwall Infirmary, Penzance.

The new West Cornwall Dispensary and Infirmary at Penzance is now nearly completed and it is hoped that it will be ready for the reception of patients in about three months. The cost of the building will be about £8000 and of this sum members of the Bolitho family have contributed £4500. The hospital comprises a central administrative block of two storeys, having a ward on each side, with various private wards, &c., attached. From the south wing of the building the new public dispensary will be built. A well-fitted operating theatre and a laundry, &c., have been added.

The Medical [illegible] *e Gloucestershire* [illegible] *trict.*

At the meeting of the Chipping Sodbury rural district council held on June 27th the resolution passed at the recent conference of representatives of the urban and rural districts comprised in the Gloucestershire combined sanitary districts urging the Chipping Sodbury rural council to reconsider the matter of the appointment of a medical officer of health and not to withdraw from the combination was brought forward. After a long discussion the council decided by a majority of two votes not to reconsider the matter. In view of this very small majority it ought not to be difficult for the Local Government Board to act upon the representation made by the 11 councils for whom Dr. Bond still acts and by exercising the powers given under Section 286 of the Public Health Act of 1875 to form a compulsory combination.

Cardiff College New Buildings.

An important step has been taken towards the removal of the reproach which has attached to the Cardiff constituent college of the University of Wales in respect of the temporary and other erections which have done duty as college buildings during the past 20 years. On June 29th His Royal Highness the Prince of Wales, the Chancellor of the University, laid the foundation stone of the new buildings which are to be erected in Cathays Park, the large open space right in the centre of Cardiff, upon which it is intended to group all the most important public buildings of the town, including the town-hall and law courts, now nearly completed. A complete scheme has been drawn up in which the college buildings are arranged around a large court having an area of 52,000 square feet. For the present the administrative and arts block together with the library, the gift of the Drapers' Company, will be erected. The medical, anatomical, public health, metallurgical, engineering, and other departments will only be proceeded with as funds are forthcoming and for the same reason the erection of the great central hall will also be delayed.

Bristol Royal Infirmary.

A large carnival has just been held in the Zoological Gardens, Bristol, in aid of the Bristol Royal Infirmary. Sir George White, Bart., the president of the infirmary, has been the leading spirit in the inception and execution of this idea for helping the infirmary and was supported by a large deeply of willing helpers. The Duchess of Beaufort became number interested in the scheme and induced a large number of ladies to take an active part in carrying it out and herself declared the carnival open. The presidents of the various medical charities in the city attended as did many of the workers for those institutions, and altogether Bristol has thoroughly given itself over to the spirit of festivity with a laudable object.

July 4th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Quater-Centenary of the Royal College of Surgeons of Edinburgh.

AT the quater-centenary celebrations of the Royal College of Surgeons of Edinburgh the following will be admitted honorary Fellows of the College:—The Director-General of the Royal Navy Medical Service; the Director-General of the Army Medical Service; the Director-General of the Indian Medical Service; the President of the Royal College of Surgeons of England; the President of the Royal College of Surgeons in Ireland; the President of the Faculty of Physicians and Surgeons of Glasgow; the President of the Royal College of Physicians of Edinburgh; the Right Hon. Lord Lister; Professor Lucas-Championnière, Paris; Professor Paul Segond, Paris; Professor Guyon, Paris; Professor Francesco Durante, professor of clinical surgery, University of Rome; Professor Vincenz Czerny, professor of surgery, Heidelberg; Professor Ernst von Bergmann, University of Berlin; Professor König, professor of surgery, Berlin; Professor Ernst Fuchs, professor of ophthalmology, University of Vienna; Professor Krönlein, professor of surgery, Zürich; Professor Carl Gustaf Lennander, professor of surgery, Upsala; Professor Saxtorph, professor of surgery, Copenhagen; Professor Halsted, professor of surgery, Johns Hopkins Hospital, Baltimore, U.S.A.; Professor William W. Keen, M.D. (hon.), professor of surgery, Jefferson Medical College, Philadelphia, U.S.A.; Professor J. Collins Warren, M.D., professor of surgery, Harvard Medical School, Boston, U.S.A.; Dr. Charles M'Burney, New York; Dr. W. J. Mayo, Rochester, Minnesota, U.S.A.; Professor Shepherd, professor of surgery, M'Gill College, Montreal, Canada; Professor Irving Cameron, professor of surgery, Toronto, Canada; Sir T. N. Fitzgerald, Melbourne, Australia; Dr. MacCormick, Sydney, Australia; Baron Yasuzumi Saneyoshi, director-general, I.J. Navy, Bureau of Medical Affairs, Tokio, Japan; Professor Anton Freiherr von Eiselsberg, professor of surgery, Vienna; Professor Poncet, professor of surgery, Lyons; Professor Terrier, Hôpital de la Pitié, Paris; Professor Subbotin, St. Petersburg; Professor Bier, Bonn; and Professor Bruno Krogius, Finland.

Medical Defence in Scotland.

In THE LANCET of Oct. 29th, 1904, p. 1239, was given an outline of an action which Dr. John Lithgow of Cleland in Lanarkshire had brought against Messrs. Thomas Gibb and Sons, Limited, trading as quarrymen. They had given to Dr. Lithgow notice summarily to terminate his appointment and had withheld the fees subsequently payable. Dr. Lithgow then brought an action on a part of his case; it was conducted for him by the Medical Defence Union and was decided in his favour. Other litigation followed, also conducted on Dr. Lithgow's side by the Union, and on June 23rd in the Sheriff's Court, Glasgow, Sheriff Boyd supported Dr. Lithgow's claim by ordering Messrs. Gibb and Sons to produce within ten days a full account of the sums retained by them from the wages of their workmen at Auchinlee Quarry, Cleland, in name of medical fees during the period from April 1st, 1903, to Feb. 11th, 1905.

St. Andrew's Ambulance Association.

The council of the St. Andrew's Ambulance Association has just issued its twenty-second annual report. During the past year 6267 calls have been made on the wagons of the association and the total number of patients conveyed since the formation of the association is now 70.629. In Glasgow alone the number of calls has been 3822. This represents an average of 10·47 daily. A brief analysis of these may be of interest. Out of the total of 3822 calls, 2474 were to accidents and 1348 were to cases of illness. In 151 cases the wagons were not required on arrival. Of the 2474 calls to accidents, 808 were from police offices, houses, and stairs; 782 were street accidents; 361 were from public works; 218 were from docks and wharves; and 154 from railways and stations. 2035 cases were taken to the Royal Infirmary, 833 to the Western Infirmary, 227 to the Victoria Infirmary, and 128 to the Maternity Hospital, the remainder being taken to their homes or to other institutions. The council draws the attention of the public to the fact that in cases of accident the ambulance wagons can be called for by any person by day or night free of all cost and responsibility. On receipt of an alarm, sent by messenger, telegraph, or telephone, a wagon will be despatched at once to the scene of the accident, and should such accident happen in any of the principal centres of the association the wagon will be under the charge of a trained attendant who, in the absence of a medical man, will temporarily dress the injuries and accompany the injured person in the wagon to his own home or to the nearest infirmary. As regards instruction in ambulance work the association has conducted and examined 379 classes in first aid to the injured " and 17 in home nursing and hygiene. The arrangement made with the Scottish Education Department for utilising the machinery of the Evening Continuation Class Code for spreading the knowledge of ambulance work has been very successful, a large number of school board classes having been conducted during the year. During the past year there were issued 4412 first-aid certificates, 330 nursing certificates, and 95 re-examination vouchers, making a total of 4837. In addition to these 1724 medallions were awarded to certificated pupils who, after attending a second course of lectures, passed an examination of a higher standard in first aid. Sanction has been given during the year for the issue of a medallion for home nursing and hygiene, and it is hoped that this will lead many to perfect themselves in these important subjects. Classes in connexion with the police forces in the counties and burghs continue to be formed with satisfactory results. The value to the public of the efficient training of the police in first aid cannot be over-estimated and the council is taking steps to insure that the new badge, bearing the name of the association, shall only be worn by certificate-holders who keep themselves efficient in ambulance work. In view of continued efficiency the council strongly recommends the formation of sections of the St. Andrew's Ambulance Corps among the trained men of the police, as an annual re-examination and inspection under the auspices of the association could then be held. In moving the adoption of the report, the Marquis of Breadalbane, who is President, remarked that the two points which struck most people about it were the enormous amount of work done during the year and the smallness of the income of the association. It was satisfactory to note, however, that the expenditure was within the income, but only by the sum of £10 4*s.* 11*d.* It was to be hoped that the public would come forward and more generously support the association as its income was entirely made up by voluntary subscriptions and its existence and public benefit depended very largely upon the amount received.

To Help the Infirmaries.

The second annual fancy dress parade organised by the cyclists of Glasgow in aid of the funds of the Royal, Western, and Victoria Infirmaries was held last Saturday. The weather was all that could be desired and the procession aroused considerable interest, the net amount collected being upwards of £300.

Death of Dr. Frank Hay Cantlie.

The death occurred on June 16th of Dr. Frank Hay Cantlie, youngest son of the late Mr. William Cantlie of Keithmore, Dufftown, and brother of Mr. James Cantlie, F.R.C.S. Eng. Dr. Cantlie, who was on his way out to China, died on board the P. and O. steamer *Formosa*. Dr. Cantlie graduated M.B. at Aberdeen in 1897 and thereafter proceeded to China. He secured the appointment of medical officer of the port of Swatow and held several important posts there, as well as having a considerable practice. Dr. Cantlie's health broke down and he returned to this country. He was for some time house surgeon of Gray's Hospital, Elgin, and later he took up his residence at Strathmore, Keith, and started practice in that town, one of his official posts being that of medical officer to the local lodge of Free Gardeners. Dr. Cantlie then removed to London, having been appointed house surgeon in the Westminster Ophthalmic Hospital. He was on his way back to China when his death occurred.

Kingseat Asylum, Aberdeen.

At a meeting of the lunacy committee of the Aberdeen City district lunacy board on June 27th Mr. John M'Gregor, convener, presiding, Dr. C. Angus, superintendent of Kingseat Lunatic Asylum, reported that the estimate of the sum required for the maintenance of the asylum for next year, including wages, clothing, lighting, food, &c., was £10,807 0*s.* 5*d.* To that sum would have to be added any deficit that might arise on the maintenance account of last year. Dr. Angus estimated that there will be about 390 patients in the asylum during the year.

Royal Army Medical Corps (Volunteers).

The annual inspection of the Aberdeen companies took place in the grounds of the Grammar School on July 1st. There was a full muster of all ranks. The inspecting officer was Colonel Hughes, principal medical officer of the North British District. Major Riddell was in command of the corps and the other officers on parade were Captains Mackintosh, Kelly, Ogston, and Fraser, Lieutenants Rorie, Mitchell, Wallace Milne, Noble, and Smart, Lieutenant and Quartermasters Innes and Cromar, and Chaplain Rev. James Smith. The men fell in at 3.15 P.M. and the inspection took place at 4 o'clock. Colonel Hughes, who arrived in his motor-car, was received with the general salute. The inspecting officer at once proceeded to make a very minute inspection of the men's uniforms and equipment. He also examined every man's sword. After inspecting No. 1 and No. 2 Companies he proceeded to inspect the Gordon Bearer Company, the transport section, and the hospital section. The corps was then formed up and marched past the saluting base. The men were then inspected in stretcher drill and first aid to the wounded. The sergeants of the various companies were also called out and had to drill their companies individually. The inspection, which lasted for over two hours, concluded with an exhibition of dressing the injuries of those who had been wounded in battle, the collecting of the wounded in the field, and transporting them to hospital, which had been constructed on the field. A short time before the inspection concluded rain began to fall heavily. The inspection was the most thorough one that the medical corps has ever undergone.

July 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Medical Examination of Trinity College.

THE Roman Catholic Archbishop of Dublin, in a speech delivered on July 2nd, made some very strong criticisms of the method by which the medical examinations of Trinity College have been recently conducted, referring especially to the action of the General Medical Council in their regard. The Provost, Dr. A. Traill, has addressed a letter to the morning papers of July 4th, traversing the charges and concluding as follows :—

> So far from the medical school of Trinity College being a "close-borough" there are at present nine external examiners and 14 University examiners, including the two Regius professors, of whom Dr. Little does not teach and Sir Charles Ball gives clinical teaching only. I have always found the Archbishop so fair, in my experience of him, in educational matters, that I am sure that if he had been aware of the above facts, he would have adhered to his first thought that "it would be much more pleasant if they were allowed to discuss the university question without invidious reference to Trinity College."

Royal College of Physicians of Ireland.

In the list of birthday honours recently conferred by the King the name of Dr. William J. Smyly, President of the Royal College of Physicians of Ireland, appears as a recipient of the honour of knighthood.

Dr. Robert Morton of Nenagh.

The many friends and patients of Dr. Robert Morton of Nenagh have recently presented him with an address and a testimonial in recognition of his long and faithful services to the district in which he has lived for so long. Dr. Morton was formerly well known in Dublin as one of the examiners in general education to the Royal College of Surgeons in Ireland. The testimonial included a cheque for £400.

The Salaries of Dispensary Medical Officers.

At the weekly meeting of the Coleraine union guardians held on July 1st it was decided that the salary of each of the dispensary medical officers should be £100, rising by increments of £10 to £150; that the salary of the workhouse medical officer should begin at £80, the maximum being £130; and that, in the event of the retirement of the workhouse medical officer, the post should be amalgamated with that of the Coleraine dispensary, the officer of which shall have a salary commencing at £130 and rising to £180.

Ulster Medical Society.

The annual meeting of the Ulster Medical Society was held in the Medical Institute, Belfast, on June 29th. From the reports presented it would appear that there is financially a balance in hand of £155 18*s.* 6*d.* There are 184 members.

The following officers were elected for the ensuing session: President: Dr. W. Calwell. Vice-Presidents: Dr. J. C. Martin (Portrush) and Dr. J. R. Davison. Treasurer: Dr. V. G. L. Fielden. Secretary: Dr. Thomas Houston. Librarian: Dr. W. L. Storey. Editorial secretary: Dr. H. Stevenson. Members of council: Dr. W. B. McQuitty, Dr. J. S. Morrow, Dr. D. J. McKinney, Mr. R. Hall, Dr. R. J. M'Cullough, and Dr. David P. Gaussen. The above with the permanent trustees (who are members of council)—Dr. J. Nelson, Dr. J. Campbell, Dr. J. A. Lindsay, Dr. A. Dempsey, Dr. John McCaw, and Mr. A. B. Mitchell—constitute the office-bearers for the ensuing session. A motion was carried that the secretary should send a vote of condolence to the friends of the late Dr. G. F. Wales, a former president of the society. It was also announced that Sir Otto Jaaffe is presenting to the society a copy of an oil portrait of Jenner which is in the National Portrait Gallery.

The Foreshore of Belfast Lough.

A meeting of property owners on the western side of the beginning of Belfast Lough was held on June 30th to protest against the continued pollution of the foreshore by the discharges from the sewage outfall works. At present about four acres are used for bacteria beds and cesspools at the outfall works of the city sewage. The corporation is now inclosing from theároblands adjoining a further space estimated at 70 acres. It is intended to cover this ground with additional bacteria beds, and it is against the odours emanating from the inclosed slobland and the bacteria beds that the ratepayers in the district are protesting.

The Health of Belfast.

At the monthly meeting of the corporation of Belfast, held on July 3rd, it was reported that between May 21st and June 11th 204 cases of zymotic disease—viz., 69 of simple continued fever, 62 of typhoid fever, 37 of scarlet fever, 27 of erysipelas, and 9 of diphtheria—had been notified. The annual death-rate was 18·5 per 1000. Scarlet fever is very mild and has been attended with a very slight mortality (only one death being recorded in four weeks); the deaths from measles still keep numerous and the epidemic is most prevalent in the east part of the city. Another case of small-pox has occurred but the source of infection from which the disease may have been contracted remains, in spite of great inquiry, a mystery. In reference to the offensive emanations from the foreshore the chairman of the public health committee said that there was ground for complaint. He hoped when the reclamation bank was completed to remedy this, and in the meantime the Antrim foreshore as far as the city boundary would be cleansed by the public health committee.

July 4th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

On Prolonged Intubation.

AT the meeting of the Pediatric Society held on June 20th M. Deguy and M. Le Play gave an account of various cases of intubation where the tube had been left in during a long time, despite a certain amount of ulceration of the larynx. In one case intubation had been performed 11 times and the tube was left in for a period altogether of 20 days. The only alternative to this procedure would have been tracheotomy. Prolonged intubation has the advantage of avoiding the risks of tracheotomy in children together with its tedious sequelæ of the healing of the wound in the trachea. M. Sevestre said that in his practice he was accustomed to perform tracheotomy when obstructions still existed after the third or at the longest the fourth intubation. For his own part he considered that prolonged intubation had many disadvantages.

The Treatment of Club-foot.

At the meeting of the Paris Hospitals Resident Medical Officers' Society held on June 22nd two interesting papers on the subject of club-foot were read. The first dealt with a case under the care of M. Péraire and was that of a youth, aged 16 years, who had suffered from irreducible talipes equino-varus. M. Péraire treated him by lengthening and suturing the tendo Achillis and by a muscular tendinous graft of the tibialis anticus with the extensor proprius hallucis and the extensor communis digitorum. The result of this was that the patient walked well and without fatigue. More than that he could wear any kind of boot and had not to wear any apparatus. The other cases referred to had been under the care of M. Monnier. They were two patients suffering from congenital equino-varus. One of them, aged five years, suffered from double talipes and had been operated on after the Phelps-Kirmisson method with a good result. The other patient, aged seven years, had right talipes equino-varus. In this child the Phelps-Kirmisson operation did not sufficiently correct the deformity so M. Monnier took out an osseous wedge, with its base towards the upper external side, at the expense of the os calcis—a procedure which, together with tenotomy of the tendo Achillis, gave an almost perfect result. This operation was practically that of Phelps-Félizet, modified owing to the youthful age of the patient by taking the osseous wedge from the os calcis and not from the cuboid.

The Physiological and Therapeutic Effects of Neuronal.

M. Marie, M. Pelletier, and M. Viollet communicated a paper to the Therapeutical Society on June 14th concerning their researches upon neuronal or bromdiethylacetamide. In toxic doses this drug paralyses successively both the unstriped and the striped muscles, especially those in the coats of the arteries. In medicinal doses—that is to say, in doses of one gramme—it is a very useful hypnotic in cases of simple insomnia and in states of mental confusion or of subacute mania. Neuronal has no cumulative effect even when it is given for many days. The dose does not require increasing and when the drug is left off no trouble apparently arises.

A Hospitals Clothing Association.

There has just been started in Paris a Hospitals Clothing Association. As its title suggests the object of the society is to distribute clothing to patients who go out of the hospitals and have to look for work. The society appeals to its supporters for articles of clothing, either new or previously used, of any kind, and for money with which it may buy such articles.

Bread as a Source of Tuberculosis.

At a recent meeting of the International Tuberculosis Society Dr. Georges Petit showed that bread is capable of being an important factor in the propagation of tuberculosis. When the various processes through which flour passes on its way to become bread are considered it is easy to understand that the successive manipulations which the dough undergoes can easily favour the introduction of the germs of tuberculosis. It is above all during the kneading process that the danger is most patent. The workman, who is called *geindre*, heaves up a large lump of dough and lets it fall, grunting as he does so. This heaving up and throwing down again of the dough are necessary to introduce air into it. When it is considered that bakers' labourers are affected with tuberculosis to the proportion of some 70 per cent. it is easy to see what facilities there are for the entrance of the tubercle bacillus into the dough. Moreover, when the bread is baked it does not attain a temperature of over 100° C. in the middle of the loaf and the slight portion of time which elapses between the baking of the bread and that of its consumption is favourable to the dissemination of the bacillus of tuberculosis. Dr. Petit said that these facts were confirmed by the experiments of Galtier and of Macé as well as by his own. The question is so important from an alimentary point of view that it would seem well to replace hand kneading by machinery.

July 4th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

A Hospital Fund in Vienna.

SEVERAL benevolent institutions have made an effort to introduce here the English system of collections in the streets for charitable institutions. Most of these institutions are kept up by the Government, but as the funds are scanty an appeal was made on behalf of sick children. The novel idea has not been a full success as yet, since the collection was combined with a fête which required a good deal of the income to cover its own expenses. Anyhow, £4000 are now available from this source and will be divided amongst two children's hospitals and several kindergärten. The new infants' milk hall, which does so much charitable work amongst the most needy and the weakest infants, will receive fully one-third of the sum to enable it to establish branch halls in some outlying district. It is proposed to repeat the appeal on a larger and more efficient scale and to use only those methods which give such good results in London. The population need only be brought to understand better than they do at present hospitals and their absolute necessity for the public welfare.

Post-graduate Lectures at the University of Vienna.

During the months of July, August, and the first half of September post-graduate lectures and courses will be held by a number of *docenten* and assistants of the clinics. As a rule the courses last for four weeks. Their object is to inform the practitioner of the progress of medicine, to introduce him to the latest methods of investigation and diagnostic technique, and to rehearse, in short, modern ways of scientific research and treatment. The fee is nearly uniform, £4 4*s*. for each course, and they offer an excellent means of practitioners keeping themselves up to date. Surgery and medicine, bacteriology and physiological chemistry will be the chief subjects of the lectures, whilst special surgery, gynæcology, and morbid anatomy will only be lectured upon if a sufficient number of gentlemen (at least four) make application.

A New Midwives Act.

Dr. Cantor has worked out the regulations for a new Midwives Act which it is proposed to bring before Parliament in its next session. The system in force hitherto is quite insufficient. The women have little education, except in the towns, and their scientific knowledge is very slight. Only a few are appointed or paid by the local authorities and the pay itself is ridiculously low. Thus they are forced to work otherwise for their living and they look upon midwifery only as their secondary occupation. An amelioration of the present state of things is not difficult. There are sufficient lying-in hospitals and obstetric wards and plenty of suitable women would apply for scholarships and instruction if their future were made safe by adequate pay. Therefore Dr. Cantor proposes that there should be created appointments for midwives, each worth from £20 to £30 a year, and that a tariff should be formed for their professional work below which tariff no midwife would be likely to go to a patient. The instruction would be compulsory, lasting one year, and an examination would have to be passed at the end of the term of instruction. A certain amount of elementary knowledge would be the *conditio sine quâ non* for entering the midwives' school. The whole country except the towns would be allotted into districts and each district would be given to not more than three midwives. They would be obliged to call in a duly qualified medical man in every abnormal case, also in cases of multiple gestation (twins, monsters), and would not be allowed to undertake any surgical or medical treatment of mother or child. And, finally, all midwives would be bound to prove their learning by obtaining a sort of diploma, without which they could not be registered.

The New Dean of the Medical Faculty.

Professor Emil Zuckerkandl, the well-known anatomist, has been elected dean of the medical faculty for the year 1905–06. It is the second time that he has been called to this coveted post of honour. Whilst in office five years ago he gained the love of the students and the esteem of his colleagues to such a degree that he has been elected unanimously for a second time within ten years.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Government Control of Vaccine Virus.

NEARLY two years ago Congress passed a law to regulate the sale of viruses, serums, toxins, and analogous products and to regulate interstate traffic in such articles. Previously anyone could make a product, label it vaccine virus, and place it on the market regardless of the impurities which it contained. In accordance with the law the officers of the Public Health Service have made an inspection of each establishment manufacturing vaccine virus in the United States and the result was that a number were found to be using old and obsolete methods, quite regardless of sanitary rules. These were required to conform to the new rules or to close their works and in several instances the latter alternative was adopted. At present there are eight producers of vaccine in this country licensed to engage in the manufacture and interstate sale of this article. These are under close supervision and their products are inspected monthly by the experts at the hygienic laboratory of the Government. The inspector is accompanied by experts and a rigid examination is made of all portions of the establishment, stables, barns, warehouses, records and animals, water-supply, disposal of refuse, and the screening of animals from insects. The samples used for testing the virus are purchased in the open market monthly and the tests are as to purity and potency. The results of the enforcement of the law for 18 months are most gratifying; the defective establishments have been eliminated and those licensed are maintaining a very high standard of excellence in all their operations.

A New School of "Medical" Practitioners.

A Bill passed the Minnesota legislature authorising a class of persons to practise "chiropractic medicine." The Governor of the State vetoed the Bill, stating that "chiropractic has not yet become a science or even a school, and at best but an untried experiment, which has produced no lasting or definite results. Among the applicants for position on this proposed board are insurance agents and men in other walks of life with absolutely no medical training whatever. The health of the public is the first essential and should be safe-guarded by every possible legal requirement, and if chiropractic must be recognised at all, those practising this so-called art should certainly be required to pass examination in the essential branches by due and regular examination before the State Medical Board, which represents the best thought and is the recognised and established standard which has been developed from the experience of the ages."

Official Report on Acetanilid Mixtures.

The first report of the Council of Pharmacy and Chemistry of the American Medical Association is on the acetanilid preparations and the results will prove very instructive to the medical profession. Specimens of the articles were bought in different cities in the open market and in original sealed packages. Each article was examined by at least two chemists. While some of the preparations are represented as being chemical compounds, the specimens examined were all found to be mixtures, the principal ingredient being acetanilid. Large quantities of these mixtures are popular remedies for headache and are freely sold to the public. The following examples are given:—Ammonol contained the following ingredients, approximately, in the proportions given: acetanilid 50, sodium bicarb. 25, and ammonium carb. 20; antikamnia: acetanilid 68, caffeine 5, citric acid 5, and sodium bicarb. 20; Koehler's headache powders: acetanilid 76 and caffeine 22; phenalgin: acetanilid 57, sodium bicarb. 29, and ammonium carb. 10.

Governmental and Private Responsibility in the Prevention of Tuberculosis.

At the recent meeting of the National Association for the Study and Prevention of Tuberculosis, the following conclusions were adopted:—"We emphasise publicly and primarily the duty of governments, especially State and municipal, in the more general founding and maintenance of sanatoria and encourage the philanthropic opportunity of private individuals to the same end; we emphasise the educational, disciplinary, and hygienic value of these sanatoria and special hospitals, not only to the segregated, instructed, and aided patients themselves, but to the general practitioner and to those patients for whom institutional treatment is not possible."

A Stringent Sanitary Law.

The legislature of the State of California has passed a law making it a misdemeanour to own, to lease, to let, or to hire any room for a lodging or sleeping apartment that contains less than 500 cubic feet of air space "in the clear" for each occupant; it is also a misdemeanour to be an occupant of such apartment. If this law is strictly enforced vast numbers of the people of that State will soon face heavy fines or a prison.

June 28th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Medical Research in India.

A RESOLUTION has been issued by the Government of India in connexion with medical research. It implies a provision for more adequate means for the scientific study of the etiology and nature of disease and admits that the former financial difficulties have disappeared. The successful administration of the Pasteur Institute at Kasauli has apparently led the Government to see at last that it only requires the necessary opportunities for the existing staff of scientific workers in India to show that they are worthy of the problems that confront them. The resolution goes so far as to say that when the scheme is developed it should no longer be necessary for officers to leave India to study the bacteriology and parasitology of tropical diseases. This is an admission of past neglect, because India should even now attract officers to it for the study of such diseases. A central research institute will be established at Kasauli and a laboratory for scientific, medical, and sanitary work at the headquarters of each provincial government. The function of the central laboratory will be original research, the preparation of curative sera, and the training of scientific workers. The provincial laboratories will apparently be for the provision of expert assistance for the provincial medical and sanitary officers, with some original research work so far as opportunities will allow. At Guindy in Madras at the King Institute there will be general research work and probably the manufacture of some curative sera. At Bombay the plague research laboratory will become the provincial laboratory and some research work will be carried on in addition to the manufacture of the prophylactic. Bengal is merely referred to as having a laboratory attached to the Medical College and at Agra Hankin's laboratory is mentioned. There is to be a similar laboratory at Rangoon where medico-legal work is to be separately done. The first director of the central research institute is to be Colonel D. Semple, R.A.M.C. (retired). It will be noted that in the resolution there is no detailed reference to the opportunities for the scientific study of tropical diseases and no school of tropical medicine is even hinted at. There is no reference to a sanitary service for India or to any scheme for sanitary investigations. There is no indication that an adequate number of original workers will be appointed free from the embarrassments of other posts. The resolution itself is couched in such general terms that it may imply either that a great deal is to be done or that the existing institutions may merely carry out the apparently excellent programme. It is desirable to know something more definite and the new Sanitary Commissioner with the Government of India, on whom the responsibility for this research work will fall, should show that some well-organised and extensive research is going to be instituted.

The Decline of the Plague Mortality.

The mortality from plague continues to fall as expected. There were only about 15,000 deaths during the past week, whereas a month ago the deaths were over 50,000 in the week. The Punjab returns but 9000 deaths, as compared with 16,000 during the previous seven days; the United Provinces, 1700 deaths, as compared with nearly 3000; Rajputana, 2400; Bengal, 695; Bombay districts, 707; Madras Presidency, 14; and Burma, 85.

June 17th.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

The New Midwives Act.

THE Government here, it would seem, is losing little time in getting to work to carry out the provisions of the Midwives Act which was passed in the closing hours of last session. The Act provides for the registration of midwives and the setting up of maternity homes for the teaching of midwives. Section 4 sets out that:—

> Every woman is entitled to be registered who satisfies the registrar that (*a*) at the commencement of this Act she had been for at least three years in *bonâ fide* practice as a midwife and that she bears a good character, provided that application for registration be made to the registrar on or before the first day of January, 1906; or (*b*) she holds a certificate in midwifery from any recognised training school in midwifery, or from the Obstetrical Society in London, or such other certificate as may be approved by the registrar; or (*c*) holds a certificate under this Act.

Section 5 says that:—

> There shall be established in New Zealand one or more State maternity hospitals where pupil nurses can, on payment of the prescribed fee, be carefully instructed in all the duties required for the welfare of mother and infant during and immediately after childbirth.

Every pupil must satisfy the examiners as to her proficiency and that she has attended lectures at a State maternity hospital or other institution recognised by the registrar as affording to its nurses sufficient training in midwifery for a period of six months in the case of a nurse registered under "The Nurses Registration Act, 1901," or of 12 months in any other case, and has attended the prescribed number of cases of labour. The Act contains machinery whereby a person may be removed from the register or suspended, when suspension appears necessary in order to prevent the spread of infection or on account of malpraxis. After Jan. 1st, 1907:—

> Every woman is liable to a fine not exceeding £20 who, not being registered under this Act, practises as a midwife, or takes or uses the name or title of a midwife (either alone or in combination with any other word or words), or any name, title, addition, or description implying that she is registered under this Act or is qualified to practise or is recognised by law as a midwife. Provided that nothing herein shall apply to any legally qualified medical practitioner, or to any woman rendering assistance in a case of emergency.

A large and commodious private hospital has been purchased in Wellington for the purpose of carrying out the provisions of the Act and a matron and an assistant matron have been appointed. The homes have been named "St. Helens Hospitals." There has undoubtedly been a scarcity of well-trained midwives in the colony and hitherto nurses desirous of taking up maternity work had either to proceed to England or to Sydney.

The Treatment of Pulmonary Consumption.

In the course of some 10 or 14 days the public of Wellington and suburbs subscribed over £2000 for the purpose of erecting annexes to the hospitals in that city and at Otaki for the treatment of pulmonary consumption. The Government will add 24*s.* to every £1 thus raised by private subscription, so that a sum of over £4400 is now available for the starting of this much-needed work. The sum may seem small to those who dwell in large places but it has to be remembered that the capital city of New Zealand has only some 49,000 inhabitants, and further, that as all public hospitals are supported by the State people are inclined to say, "Oh, let the Government put them up." The success of the appeal is largely due to the medical profession generally and to Dr. A. K. Newman and Dr. T. H. A. Valintine in particular. When the scheme outlined by the Minister of Health has been carried out in its entirety New Zealand will undoubtedly have done something to check the march of consumption. The idea is to erect small annexes in connexion with country hospitals situated in districts which have a reputation for excellence of climate. Patients will require to enter the hospital belonging to their several districts but later they may be drafted into the Government sanatorium at Cambridge. The cost of administering these annexes close to a general hospital will be much less than that of a separate institution, while from a preventive point of view their value will be almost as great. The patient will be housed in such a manner as to give him the best chance of recovery, he will be taught the value of fresh air, cleanliness, and a reversion to a more natural mode of life, while the destruction of the sputum will be assured.

Honour for the Inspector-General of Asylums.

A well-deserved tribute has been paid to our Inspector-General of Asylums (Dr. Macgregor) by his *alma mater* (Aberdeen) in presenting him with the LL.D. The acknowledged excellence of our asylums—that is, as regards all that pertains to their management—is in a large measure due to the firmness and foresight of Dr. Macgregor. An uncompromising opponent of all State coddling and salvation of the body politic through eleemosynary treatment, it has been his lot to run the hospitals and asylums of the most democratic of His Majesty's colonies.

The Sad Death of a Young Woman at a Private Hospital.

An event in Christchurch recently illustrates how sometimes the best-intentioned procedure may result in great wrong. According to the evidence given at the inquest a young woman who, the medical attendant stated, suffered from hysteria was sent to a private hospital. She became violent and was placed in a "strait jacket" in addition to being strapped to the bed by the feet as well as by the neck. It would appear that she was left alone for some time. On returning the nurse found her lying dead, with her head over the side of the bed. Dr. W. H. Symes, who sent the case to the hospital, stated that he did not feel justified in certifying that she was insane. Dr. B. M. Moorhouse corroborated the statement. Dr. Symes stated that he had sent many cases to this particular home and had always been satisfied with the way in which the hospital had been conducted. A juryman asked whether, if the patient had been sent to the asylum, "she would not have been alive now." The coroner said, Yes. He commented upon the fact that the nurse actually in attendance on the deceased admitted that she had had no previous training with respect to such cases. The jury found that the deceased had died from suffocation and added a rider to the effect that such cases should not be allowed to be treated in private homes. The hospital in question was licensed by the Health Department. The certificate of character and ability was signed by two well-known medical men of standing in Christchurch. The building had been inspected carefully. An accident such as this points to the need of more frequent inspection, though it is difficult to see how a health official could have averted it unless he had been actually present at the time.

Wellington, May 20th.

Obituary.

JAMES MACNABB CUNINGHAM, C.S.I., M.D. EDIN., LL.D., K.H.S.,

SURGEON-GENERAL, I.M.S.

THE death of Surgeon-General J. M. Cuningham, which took place at Buckingham Palace-mansions on June 26th last, at the age of 76 years, removed an officer of the Indian Medical Department of long and distinguished service who had in his time occupied a very notable and influential position. He was intimately acquainted with Sir John (afterwards Lord) Lawrence and other Viceroys of India and socially, as well as in respect of his intellectual qualifications, was much esteemed and liked by Indian officials and men in authority. Surgeon-General Cuningham during his career filled some of the highest medical and sanitary posts in connexion with the Government of India and was at one time the administrative head of the service to which he belonged. He retired from the service in 1885, having entered the H.E.I.C.S. so long ago as in 1851. He was a graduate of the University of Edinburgh which in 1892 conferred upon him the honorary degree of LL.D. After having joined and held various appointments in the Bengal Medical Service he became secretary to the Sanitary Commissioner and was next appointed Sanitary Commissioner of Bengal, and afterwards (in 1875) as Sanitary Commissioner with the Government of India he had charge of the whole sanitary department of that country and was for many years the special adviser of its Government. His name also became widely known in connexion with the long series of annual reports which were issued during the time he occupied that office. In 1880 he became surgeon-general with administrative charge of the medical service in India. When he retired in 1885 he was awarded a Companionship of the Star of India and three years later he became honorary surgeon to Queen Victoria. He was a member of the Army Sanitary Committee from 1891 to 1896, and in 1894 he represented the Government of India at the Paris International Sanitary Conference. He was the author of a treatise on "Cholera: What can the State do to prevent it?" This is neither the time nor the place to discuss the policy adopted and followed by Surgeon-General Cuningham or to enlarge upon the views he held in regard to the origin and causes of Indian diseases and the best way of dealing with them, more especially with those of an epidemic character. Surgeon-General Cuningham was a man of both boldness and ability. He held very decided opinions in regard to these matters and set them forth in very plain and lucid terms in his reports, adhering as closely as he could in so doing to arguments based upon facts and figures, to the exclusion of all theoretical views, and especially to such as seemed to him to be demonstrated insufficiently to warrant the interference of the Government or the outlay of public money in their behalf. Endowed with an eminently common-sense and judicial rather than a scientific type of mind he always sought to look on his advisory duties to the Government not only from the standpoint of medical science but from that also of the statesman who has to incur the responsibility of giving effect to the advice which he receives.

DONALD URQUHART MACLENNAN, M.D. EDIN.,

MEDICAL OFFICER OF HEALTH, WIDNES, LANCASHIRE.

Dr. Donald Urquhart MacLennan was born at Milton, Glen Urquhart, on April 5th, 1851. He was the second of three brothers who all became members of the medical profession. He received his early training at the parish school of his native place—a glen famous for its beautiful scenery and romantic surroundings. He attended arts classes for one or two sessions at the University of Glasgow, but his medical studies were pursued at the University of Edinburgh, where he graduated as M.B., C.M. in 1878 and as M.D. in 1882. For a year after graduation he acted as assistant to the late Dr. Cran of Salford. In the year 1880 he commenced practice at Widnes and there he spent 25 busy years. In later years he became medical officer of health of the newly formed municipal borough, and those who remember Widnes 20 years ago will be ready to appreciate how much the chemical town owes to his energy and skill. Dr. MacLennan's professional career was one of hard and strenuous work. He was an active general practitioner of the best type and secured a large practice in the town and district.

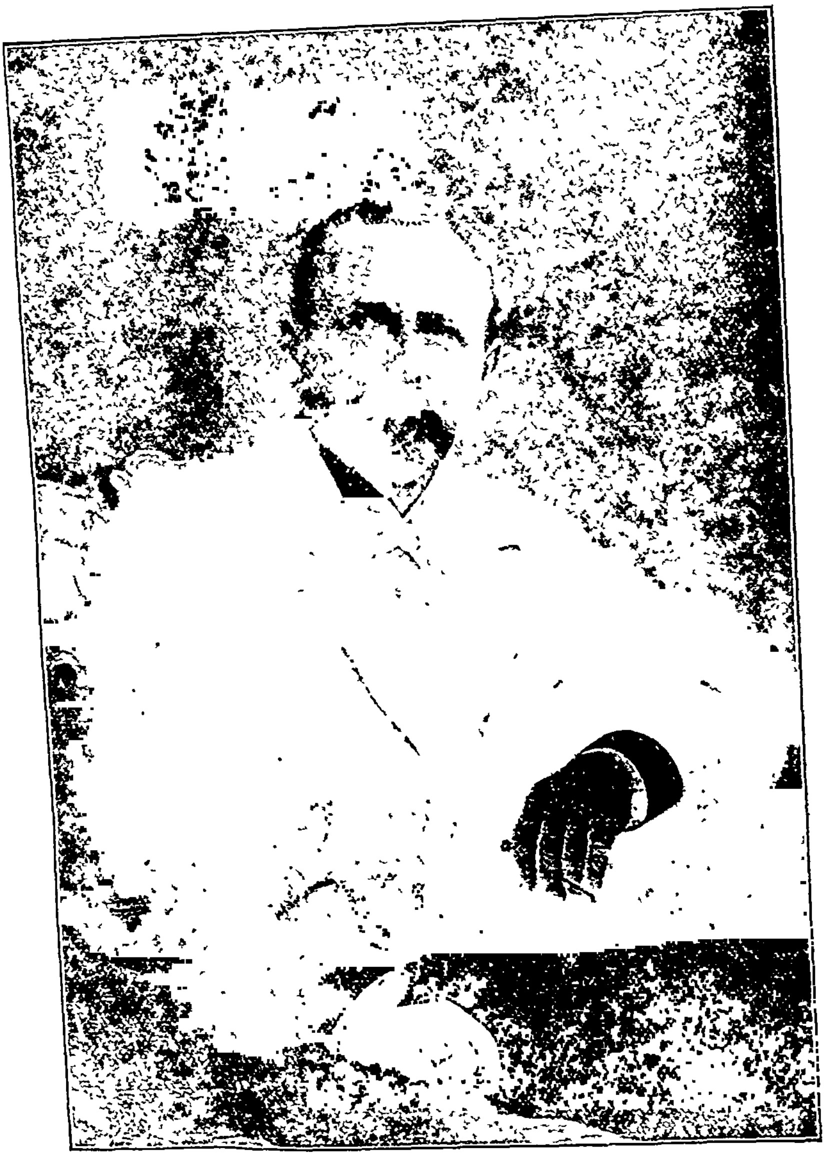
A Highlander to the backbone, Dr. MacLennan was possessed of a buoyancy and exuberance of spirits that are alien to the Scoto-Celtic temperament. Good at his work, an active and vigorous personality, and generous to a fault, he was a bright, breezy companion—a man who made friends and kept them. Deeply interested in all things Celtic, he was one of the founders and original members of the Caledonian Medical Society and was president of the society in the year 1884. He was also chiefly instrumental in founding the Widnes and District Medical Society in 1895 and he was its first president. He often referred with pride to the fact that he had taken an active part in founding and establishing two distinct medical societies—one connected with his fatherland and the other with the town of his adoption. Eight years ago he broke down with a serious attack of pleurisy which developed into empyema. From this he made a good recovery but about a year ago hepatic troubles manifested themselves and despite the most careful nursing and all that his medical friends could do for him they pursued their sequence to the fatal end. He faced the inevitable, not only with fortitude but with a cheerfulness, brightness, and patience that were marvellous, particularly in a man of his untiring and indomitable energy. He was attended in his illness by his friend, Dr. J. R. Logan of Liverpool.

The funeral took place on June 7th and the ceremony was attended by the mayor, corporation, and officials, by many hundreds of the townspeople, and by numerous sorrowing friends from a distance. Dr. MacLennan is survived by his widow and five children. His eldest son is studying medicine at the University of Edinburgh.

PROFESSOR VON MIKULICZ-RADECKI,

PROFESSOR OF SURGERY IN THE UNIVERSITY OF BRESLAU.

OUR Berlin correspondent has already given our readers a note upon the career of the celebrated surgeon who is known to all Englishmen as Mikulicz and not by his full name as von Mikulicz-Radecki, and whose death took place on June 14th at Breslau, where he was professor of surgery. We may supplement this account by a few details. Professor Mikulicz was born in 1850 at Czernowitz; he studied at Vienna and received his degrees at the age of 25 years. After being for some time attached to the Universities of Cracow and Königsberg, he was in 1890 appointed to Breslau and raised the reputation of the surgical clinic there, till it was regarded as one of the greatest centres of surgical study in Germany. We need not here repeat what we have already published. In England Professor Mikulicz was best known as the coadjutor with Professor von Bergmann of Berlin and Professor von Bruns of Tubingen in "A System of Practical Surgery," a review of which appeared in our columns quite recently. This work, in five volumes, which forms practically a complete surgical library in itself, was so highly appreciated by the profession of Germany that a second edition of the earlier volumes was asked for before the later ones were published. Italian and Spanish translations appeared almost immediately but the English translation by Professor W. T. Bull (the book which was reviewed on June 24th, p. 1723) has only recently been issued. This English translation has the advantage of being made from the second German edition and possesses over 100 full-page plates which were not given in the original.



PROFESSOR VON MIKULICZ-RADECKI.

The additions made to surgery by Mikulicz are not connected with any special department but are spread all over the science of surgery. With two operations, however, will his name be chiefly connected. Vladimirof had designed in 1872 an osteoplastic resection of the foot for disease of the tarsus but Mikulicz was quite unaware of what Vladimirof had done when he performed his operation. It consists essentially in the removal of the soft parts covering the heel, with the astragalus and os calcis, so that the cuboid and scaphoid are brought into contact with the same surface of the tibia and fibula and thus a condition of marked talipes equinus is produced. The operation is ingenious but it is even yet too soon to express an opinion as to its ultimate position in operative surgery. The other chief contribution to surgery is the operation of pyloroplasty. The idea of relieving a fibrous stricture of the pylorus by dividing it longitudinally and then suturing it transversely appeared to have occurred almost simultaneously to Heineke and to Mikulicz and therefore the operation is now frequently known by both their names. The device is applicable to many portions of the alimentary canal and, indeed, to all tubular viscera, and it has attained deservedly to a widespread employment, though in great part its use for the relief of fibrous stenosis of the pylorus has given way to gastro enterostomy. As an operator Mikulicz was bold and ingenious, clever in devising expedients to overcome difficulties encountered, and skilful in carrying out the operations which he had devised.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced.—Dr. Joseph Krieger, who was until a couple of years ago head of the medical department of Alsace and Lorraine. His published papers deal with a variety of hygienic subjects, especially with the geographical distribution of disease and epidemiology. He was 71 years of age.—Dr. Viktor Wehr, professor of surgery in Lemberg, at the age of 52 years.—Dr. Robert King, professor of gynæcology in the St. Louis College of Physicians and Surgeons.—Dr. Peters, author of numerous papers on the pharmacology of new drugs.—Dr. Consiglio, *privat-docent* of physiology in Palermo.—Dr. A. Le Roy, formerly surgeon to the Rouen hospitals.—Dr. Karl Wernicke, professor of mental diseases in Halle, and author of many papers and several large works on the brain and its pathology. He was 57 years of age. The cause of death was a bicycle accident which he met with in the Gerathal.—Dr. Georg Mayer, the well-known Aix-la-Chapelle physician, at the age of 80 years.—Dr. von Hüttenbrenner, formerly director of the Karolin Hospital, Vienna.—Dr. Feodor Zavarikin, late professor of histology and embryology in the St. Petersburg Military Medical Academy.—Dr. August von Wegner, Surgeon-General in the Prussian Army and for many years body physician to the Empress Frederick.

Medical News.

University of Oxford.—Dr. James Ritchie, M.A., B.Sc., Fellow of New College, Reader in Pathology, has been constituted Professor of Pathology so long as he holds the aforesaid readership.—At examinations held recently the following candidates were successful:—

First M.B. Examinations.

Organic Chemistry.—H. O. S. Gibson, New College; G. D. Knox, Balliol; G. E. Neligan, Exeter; H. W. Scott-Wilson, Queen's; W. W. Wagstaffe, New College; and R. O. Ward, Queen's.

Materia Medica and Pharmacy.—P. P. Andrews, University; D. C. Dobell, Christ Church; G. E. Downs and H. J. Fry, Magdalen; H. E. Gibson, Queen's; G. H. Hunt, Christ Church; G. J. Z. Jessell, University; G. E. Neligan, Exeter; H. P. Newsholme, Balliol; J. A. Noble, Queen's; E. W. M. H. Phillips, Jesus; and T. S. Wright, Brasenose.

Human Anatomy and Human Physiology.—M. B. Bates, St. John's; A. W. Burnyeat, Queen's; G. D. Carpenter, New College; C. D. H. Corbett and G. H. Crosfield, University; G. R. Girdlestone and S. Hartill, New College; B. G. Klein, Christ Church; and T. R. Walker, Hertford.

Second M.B. Examinations.

Forensic Medicine and Hygiene.—H. H. Baker, University; H. A. Barnes, Keble; O. E. Berkeley-Hill, Trinity; L. T. Burra, University; P. J. Dear, New College; J. S. C. Douglas, Christ Church; E. L. Farncombe and J. H. Hebb, St. John's; R. Jamison, Trinity; R. C. Jewesbury, Christ Church; G. A. Jones, Magdalen; S. Nockolds and L. J. J. Orpen, Keble; C. J. Pinching, St. John's; J. G. Priestley, Christ Church; C. A. Smallhorn, Wadham; B. H. Spilsbury, Magdalen; H. G. F. Spurrell, Merton; and H. C. Squires, Hertford.

Pathology.—H. H. Baker, University; C. Beards, Jesus; H. B. Billups, Worcester; H. H. Carleton, Keble; D. Davidson, Brasenose; J. S. C. Douglas, Christ Church; E. L. Farncombe, St. John's; G. M. Johnson and G. A. Jones, Magdalen; O. G. F. Luhn, Christ Church; S. Nockolds, Keble; C. J. Pinching, St. John's; H. R. Ramsbotham, Brasenose; H. S. Souttar, Queen's; H. C. Squires, Hertford; A. S. J. Thompson, Queen's; and A. P. Yonge, Exeter.

Medicine, Surgery, and Midwifery.—H. A. Barnes, Keble; E. L. Farncombe and J. H. Hebb, St. John's; R. Jameson, Trinity; R. C. Jewesbury and J. G. Priestley, Christ Church; C. A. Smallhorn, Wadham; and B. H. Spilsbury, Magdalen.

Master in Surgery.

A. C. Goodwin, B.M., Keble; and O. W. Richards, B.M., New College.

University of Cambridge.—At the final congregations of the term, held on June 20th, the honorary degree of LL.D. was conferred on the Right Hon. Earl Cromer, in the presence of H.R.H the Duchess of Albany, and the following were admitted to medical degrees:—

M.D.—F. J. Lidderdale, Trinity; and F. J. Child, Christ's.

M.B.—D. V. Cow, Trinity; T. J. Fauldes, Clare; R. E. G. Gray, Pembroke; G L. Crimp, Caius; H. Spurrier, Caius; and R. A. Clapham; Emmanuel.

B.C.—W. G. Howarth, King's; R. E. G. Gray, Pembroke; H. Spurrier, Caius; and E. Lloyd, Emmanuel.

During the academical year just closed 30 M.D. degrees, six Sc.D. degrees, two M.C. degrees, 62 M.B. degrees, and 59 B.C. degrees were conferred.—On June 27th the University of Durham held a convocation in the Castle Hall, at which the degree of Doctor of Civil Law, *honoris causâ*, was conferred on Dr. Donald MacAlister, St. John's College, President of the General Medical Council. Dr. MacAlister was presented to the Warden and Proctors by Sir George Philipson, Caius College, professor of medicine in the University of Durham.

University of Leeds.—A congregation of the University was held in the town hall on July 1st, when certain degrees were conferred by the Vice-Chancellor on associates of the Yorkshire College and on other students who, having attended complete courses of studies in the Yorkshire College, had graduated in Victoria University or in other universities of the United Kingdom. In the latter category degrees in medicine were conferred on the following:—

Doctor of Medicine.—Edward Turton, M.D. Vict.

Bachelor of Medicine.—George Lee Wells, M.B., B.S. Lond., Alfred Featherstone Kellett, M.B Cantab., Arthur Manknell, M.B. Lond., Stephen Leonard Butterworth Wilks, M.D., B.S. Lond., Douglas Seaton, M.B. Vict., Ralph Hopton, M.D., B.S. Lond., Charles William Eames, M.B., C.M. Edin., John Broadley, M.B. Lond., Francis Darlow, M.B. Vict., Alexander Mackenzie, M.A., M.B., B.C. Cantab., Charles Herbert Moorhouse, M.B. Vict., Harry Stansfield, M.B Vict., William Jenkins Webb Anderson, M.B. Vict., Charles Henry Greenwood, M.B. Vict.. John Arthur Reed, M.B. Vict., Ernest William Spink, M.D Lond., Charles Rudolph Willans, M.B. Vict., Henry Brown, M.B. Vict., William Atkinson Stott, M.B. Vict., Robert George Macdonald Ladell, M.B. Vict., Leonard Ralph Braithwaite, M.B. Vict., Harry Maffin M.B. Vict., Crawfurd Tait Matthews, M.B. Vict., Frederick Percy Hewetson Birtwhistle, M.B. Vict., Wilfred Edward Brierley, M.B. Vict., Edward Cundall, M.B. Vict.. Arthur Maslen Deane, M.B. Vict., Frederic William Marshall Greaves M.B. Vict., Frederick William Hayes, M.B. Vict., James Huntly Legge, M.B. Lond, Herbert James Macvean, M.B. Vict., Bertram Suggit, M.B. Vict., Herbert Tomlin, M.B. Vict., and William Herbert Smailes, M.B. Lond.

Among those degrees conferred on the results of examinations of the University was the following:—

Doctor of Medicine.—Arthur Stanley Parkinson.

On June 30th degrees were conferred by the Vice-Chancellor on the heads of certain departments and on certain members of the staff of the General Infirmary at Leeds which is closely associated in its work with the University. Among these the following were conferred:—

Master of Science.—C. J. Wright, M.R.C.S. Eng., William Bevan Lewis, M.R.C S. Eng., L.R.C.P. Lond., W. H. Brown, F.R.C.S. Irel., M.R.C.S. Eng, Harry Littlewood, F.R.C.S. Eng., and H. Secker Walker, F.R.C.S. Eng.

The written examinations for degrees in medicine and surgery will begin on July 10th and the practical and *vivâ voce* examinations on the 13th. Degrees will be conferred by the Vice-Chancellor on July 22nd.—By resolution of the Court the degree of M.D. was conferred *in absentiâ* on William Walter Stoney, M.D. Vict., residing at Kimberley, South Africa.

Foreign University Intelligence.—*Baltimore (Johns Hopkins University):* Dr. W. S. Thayer has been appointed to the chair of Clinical Medicine.—*Bologna:* Dr. Crisafulli of Naples has been recognised as *privat-docent* of Mental Diseases.—*Breslau:* Dr. Bernhard Heile has been recognised as *privat-docent* of Surgery.—*Clausenberg:* Dr. Elemer Veress has been recognised as *privat-docent* of Physiology and Dr. Julius Filep as *privat-docent* of Hygiene.—*Giessen:* Dr. O. Frank of Munich has been offered the chair of Physiology with the Directorship of the Physiological Institute as successor to the late Professor Eckhard.—*Gottingen:* Dr. Birnbaum has been recognised as *privat-docent* of Gynæcology.—*Konigsberg:* Dr. R. Stich of Nürnberg has been recognised as *privat-docent* of Surgery. Dr. Berthold, Extraordinary Professor of Laryngology and Otology, is about to resign.—*Munich:* Dr. Karl Hörmann has been recognised as *privat-docent* of Gynæcology.—*Odessa:* Dr. Sadowski of St. Petersburg has been appointed to the chair of Gynæcology.—*Paris:* Dr. Wertheimer of Lille and Dr. Yersin of Paris have been elected Corresponding Members of the Paris Academy of Medicine.—*Prague (Bohemian University):* Dr. Kamil v. Lhotak has been recognised as *privat-docent* of Pharmacology.—*Rostock:* Dr. Brüning of Leipsic has been recognised as *privat-docent* of Children's Diseases.—*Vienna:* Dr. Anton Brosch has been recognised as *privat-docent* of Pathological Anatomy; Dr. Otto Ritter v. Furth as *privat-docent* of Medical Chemistry; and Dr. Otto Marburg as *privat-docent* of Neurology.

The Russian Censor and Medical Literature.—In view of the extraordinary difficulties put in the way of the publication of the report of the Pirogoff Congress and of the *Journal of the Pirogoff Medical Society* by the censor, the *Novoe Vremya* states that the managers of these two publications have issued a notice explaining the necessity of suspending the publication of the report and of the journal till better times arrive for the Russian press.

Brussels Medical Graduates' Association.—The annual meeting and dinner of this association will be held on Thursday, July 13th, at 7 o'clock, at the New Gaiety Restaurant, Strand, London. Members desirous of attending are requested to notify the honorary secretary, Dr. F. H. Edwards, Camberwell House, London, S.E.

The League of Mercy.—On July 1st, at the invitation of the Prince and Princess of Wales, a garden party was held at Marlborough House in connexion with the League of Mercy. While the majority of the guests, who included the presidents, lady presidents, vice-presidents, and members of the league, were assembling in the grounds a meeting was held in the drawing room of Marlborough House when the report of the year was presented. The Prince of Wales said:—

> I am much gratified to learn from the report that another most successful year has been completed and that the large sum of £14,000 has been handed over to King Edward's Hospital Fund. This makes a total contribution of £46,000 during the five years that the league has been in existence. This steady increase is, indeed, most satisfactory and I am well aware that such results could not have been attained without much personal trouble and sacrifice of time on the part of the members of the league. The Princess desires me to express her regret that she is unable to be present and in her name, as well as in my own, I desire once more to thank you for the splendid work you have done on behalf of the league.

The meeting then adjourned to the gardens where the Prince, accompanied by Prince Edward and Prince Albert, presented the badge of the Order of Mercy to those ladies and gentlemen who had been awarded this honour for their work on behalf of the league. During the afternoon the band of the Royal Marines played a selection of music and refreshments were served at a buffet which had been specially erected to meet the needs of the 1000 guests who had received invitations.

Middlesex Hospital.—A special court of governors of this hospital was held on June 30th under the presidency of the Duke of Northumberland to consider the notification from the King Edward's Hospital Fund for London that no grants would be made from the King's Fund to any hospitals which make payments to their medical schools out of general funds subscribed for the relief of the sick poor. The Duke of Northumberland pointed out to the governors that the welfare of the sick throughout the whole land and the character of the medical profession would be affected by their decision on the connexion between the medical schools and the hospitals and the training which those schools could afford to give their students. Sir Richard Douglas Powell proposed a motion that it was the desire of the special court of governors that the medical school of Middlesex Hospital should be maintained and that such assistance as might be required for that purpose should be provided by the hospital or by a special fund raised for the purpose. This was seconded by Mr. Henry Morris who urged the desirability of starting a separate fund for medical education. The motion was then put to the meeting and was carried unanimously. Immediately after this Lord Derby proposed a motion authorising the hospital authorities to set aside out of the annual subscriptions such sums as might from time to time be required to effect the maintenance of the medical school and that as evidence of such authority the subscribers to the hospital should be asked and recommended to sign and to return to the hospital a form drawn up for that purpose. Lord Derby spoke for a short time in support of his proposition and contended that the hospital reaped benefit from the services of the medical students. The hospital and the medical school worked together for the advancement of medical skill and for the relief of suffering, and in that way were inseparably connected. Lord Cheylesmore, in seconding the motion, asserted that if the medical school were abolished the expenses of the hospital would be increased. The 504 governors of the hospital had been circularised and only five refusals had been received from governors who declined to join in the proposed scheme for setting aside out of the annual subscriptions such sums as might be necessary for the maintenance of the medical school. This motion, on being put to the meeting, was carried unanimously, and the proceedings terminated with a formal sanction being given for a sum of money to be expended in improvements connected with the operating theatre.

Medical Barristers.—On July 5th five medical men were called to the Bar on "call night" of Trinity term at the four Inns of Court. Harold Coates, M.D., D.P.H. Vict., and John Francis Butler-Hogan, M.D. Brux., D.P.H. Cantab., LL.B., were students at Gray's Inn; Frederick Sherman Toogood, M.D. Lond., at the Middle Temple; James Scott Tew, M.D. Durh., D.P.H. Cantab., at the Inner Temple; and William Robert Bryett, M.D. Lond., at Lincoln's Inn.

The Odessa correspondent of the *Novoe Vremya* announces that the dean of the medical faculty of the Novorossisk University, Podvisotscki, has been appointed director of the Imperial Institute of Experimental Medicine.

Donations and Bequests.—By the will of Catherine, Countess of Stamford and Warrington, £500 are bequeathed to the General Infirmary, Leicester, in aid of the Children's Hospital; £200 to the Queen's Hospital, Birmingham; and £200 to the General Hospital, Birmingham.—Mr. Wyndham Francis Cook of Cadogan-square, a partner in the firm of Messrs. Cook, Son, and Co., of St. Paul's Churchyard and of Manchester, has bequeathed £25,000 to any central hospital fund in such proportions as his executors shall deem fit (of this sum £12,500 have been already given to the Metropolitan Hospital Sunday Fund), and £1000 to the Royal Ophthalmic Hospital, Moorfields.—Under the will of Miss Clara Maud Petter, of Leeholme, Bournemouth, the Royal Victoria Hospital at Bournemouth and the North Devon Infirmary at Barnstaple each receives £500. The Royal Hospital for Incurables receives £300.—Mrs. Mary Ada Mocatta has bequeathed by her will £300 to University College Hospital and £200 each to the London Hospital, St. Mary's Hospital, the Metropolitan and National Nursing Association, and Guy's Hospital.

Civil Hospitals and Dispensaries of the United Provinces (India).—The inspector general of civil hospitals of the United Provinces, Colonel C. H. Joubert, I.M.S., in his triennial report, dated 1905, dealing with the years 1902–04, points out that relaxation of the provincial rule by which a civil surgeon lost his lien on the civil station from which he took furlough has been followed during the years 1903 and 1904 by the excellent result that a considerable proportion of the senior officers holding good appointments have taken long furlough and have had a much needed opportunity of putting themselves in line with modern progress in Europe. It is essential for medical officers, however good they may be, to see as often as possible the work of other men in England. The rule formerly in force in the United Provinces was a fatal bar to this. On Jan. 1st, 1902, there were 485 hospitals and dispensaries of all classes open; on Dec. 31st, 1904, there were 508. This represents a net gain during the three years under review of 23 institutions. During the year 1904 13 new dispensaries were opened and five were closed. A Government order criticising the report is appended and in it the Lieutenant Governor "desires to acknowledge the energy and zeal displayed by Colonel Joubert in stimulating the medical progress of the province and the ready help and coöperation which has been afforded to him by civil surgeons. In particular the thanks of the Government are due to Colonel Joubert for the great interest which he has taken in the Agra medical school."

Sussex County Hospital: Stephen Ralli Memorial.—The opening and dedication of the bacteriological and pathological laboratory with which the Sussex County Hospital has been endowed by Mrs. Stephen Ralli as a memorial of her late husband took place at the hospital on June 29th. Despite the wet weather the marquee erected adjoining the laboratory was crowded. The memorial laboratory is situated in a two-storey block within a few yards of the hospital and comprises five rooms. On the ground floor is the preparation room facing the entrance; on the left of the entry is the chemical room from which access is gained by a swing door to the bacteriological room and the pathologist's room. The bacteriological room measures 19 feet 2 inches by 11 feet 7 inches, is well lighted on the east and south, and has a teak bench for four workers on the south and a slate bench on the north for embedding oven, microtomes, water blast, incubators, &c. The chemical room is 12 feet 7 inches by

23 feet 1 inch high and has teak benches, burette shelf, hot and cold water, gas, electric light, a fume cupboard, centrifuge, &c., and is well stocked with chemicals and glass ware. On the second floor is placed the photographic room. The block includes also the hospital post-mortem room and lecture room which form together a complete pathological institute. The pathological institute is intended for the clinical and pathological research of the hospital and is available to all medical practitioners at the usual fees. It thus can assist materially in the detection, prevention, and treatment of disease.

CENTENARIANS.—Mrs. Metherell of Tavistock, Devon, on May 24th celebrated the 101st anniversary of her birth.—Mr. John Bennett of Bradworthy, Devon, died on May 26th. He was a churchwarden of the parish church up to within a month of his death and the church register shows that he was baptised on May 6th, 1805.—In the *Times* of June 20th the Brussels correspondent stated that a Belgian lady, Madame Rolland of Seneffe, completed her 104th year on June 12th. She is credited in Belgium with being the only surviving witness of the battle of Waterloo.—Mrs. Mary Parsons of Enmore Green, Shaftesbury, Dorset, died on June 18th at the age of 104 years.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at 6, Suffolk-street, Pall Mall, London, on June 29th, when Dr. F. H. Champneys occupied the chair. The first business on the agenda was the consideration of a communication from the Breconshire county council transmitting a report and scheme on the administration of the Midwives Act dealing more particularly with the details concerning the local administration of its provisions. The Board directed its secretary to thank the Breconshire county council for the report and scheme. The next question before the Board was with regard to the number of examinations for midwives to be held during the year by the Central Midwives Board. On this subject a memorial had been sent from the committee of the Queen Victoria Jubilee Institute for Nurses protesting against the recent decision of the Board to hold four examinations in the year instead of three and asking the Board to reconsider its decision. A memorial was received to the same effect from the executive committee of the Association for Promoting the Training and Supply of Midwives and a letter to the same purport was sent to the Board from the warden and matron of the Salvation Army Maternity Hospital. This matter was considered at some length by the Board and it was finally decided that all the institutions concerned in the question of examinations should be informed that the Board proposed to hold a conference with them on the subject on July 29th.

CONVERSAZIONE AT KING'S COLLEGE, LONDON.—A conversazione was held at King's College, London, on June 29th, and the spacious buildings of the institution were filled with interested guests who thoroughly enjoyed the various entertainments that were provided for their amusement and instruction. In the grand entrance hall the principal of the college and Mrs. Headlam, with the deans and members of the staff, received the visitors on arrival. An organ recital in the chapel by Professor J. E. Vernham rewarded those who came early and this was followed by a lantern exhibition in the architectural class room. At the same time demonstrations were given in the electrical engineering laboratory and in the geological laboratory there was a lantern exhibition of reptiles from the Trias. There was a band in the entrance hall and another on the terrace for those who were not attracted by the exhibits in the museum and there were concerts in the large hall, followed by a dramatic entertainment which drew a large audience. On the second floor of the building in the physiological laboratory the microscopical preparations exhibited by Professor W. D. Halliburton and Dr. H. W. Lyle were carefully studied by a great number of those present. In room No. 27 Dr. C. S. Myers exhibited apparatus for the measurement of sensory acuity. The particular apparatus that seemed to astonish the visitors most was that known by the name of the Muller-Lyer illusion In room No. 29 Professor Herbert Jackson and Mr. Northall-Laurie were kept busily engaged showing the results of experiments of crystallisation under polarised light and demonstrating the differences between the various systems of crystals. In the opinion of Professor Jackson the value of using polarised light with the microscope was worthy of more attention from a medical point of view. The authorities had provided a large number of stewards who supplied visitors with information of all kinds and those concerned in the management of this conversazione must be congratulated on the very successful results of their efforts.

VACCINATION GRANT.—Mr. J. D. Staple, public vaccinator for the Ashley district of the Bristol Union, has been awarded the grant for successful vaccination by the Local Government Board for the fifth consecutive year.

RUSSIAN REPRESENTATIVES AT THE LISBON CONGRESS OF MEDICINE.—The Military Medical Academy having been invited to take part in the International Congress of Medicine to be held in Lisbon next year has selected Professor G. E. Rein and Professor I. P. Pawlow to attend as its representatives.

BRITISH DENTAL ASSOCIATION.—The central counties branch of the British Dental Association held its annual meetings in Leicester on June 30th and July 1st. At the annual dinner on Friday evening, which was attended by a number of local medical men, Mr. W. E. Harding (Shrewsbury), in replying to the toast of "The Association," expressed the hope that the dental profession would, by the help of the British Medical Association, shortly succeed in getting the Dental Act amended. No doubt there would be opposition encountered from some quarters but by hard, persistent work they ought to succeed. Mr. A. T. Hilder, the outgoing President, also replied to the toast. Mr. H. R. F. Brooks (Banbury), in submitting the toast of "The Medical Profession" said that the Bill for the amendment of the Dental Act was of the greatest possible importance, and no effort should be spared to get it through Parliament. The British Dental Association, which was formed on similar lines to the British Medical Association, had striven persistently for the uplifting of the profession. Mr. G. C. Franklin, the President-elect of the British Medical Association, said he thought that the great danger to both his own and the dental profession was the number of men joining them of inferior education. He hoped before long to see more stringent regulations with regard to the early examinations. When they obtained these both professions would benefit by having their ranks strengthened by the inclusion of a better stamp of men—men who had passed through the universities and held university degrees. Dr. F. M. Pope also replied, paying a tribute to the great assistance which the dental profession rendered to the medical profession.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—The annual dinner of the Poor-law Medical Officers' Association of England and Wales was held in the Oak Room of the Trocadéro Restaurant, London, on June 27th, Surgeon-General G. J. H. Evatt, the President of the association, being in the chair. The annual general meeting of the members took place just before the dinner and the report of the council for the year described how endeavours had been made to further the interests of Poor-law medical officers, including public vaccinators. At the end of last year an attempt was made by a London board of guardians to appoint a medical superintendent to a workhouse infirmary with a salary to include vaccination fees, but in consequence of the representations made by the council of the association the Local Government Board refused its sanction to the proposed arrangements. Among other cases dealt with by the council there was one in which duties were sought to be imposed on a district medical officer contrary to the Poor-law Orders; in a second an attempt was made by a certain board of guardians to elect its medical officers annually so as to take away all security of tenure. In a third case a serious complaint had been made against a district medical officer to the Local Government Board. Upwards of 50 new members had joined the association during the past year. After the usual loyal toasts Mr. Andrew Clark proposed "The Poor-law Medical Officers' Association." He said that the association had lasted more than 100 years and showed how the discussions at the meetings of members tended to the public good. Dr. Major Greenwood, the honorary secretary, in responding, drew a harrowing picture of the hardships endured by the Poor-law medical officers in out-of-the way districts. He contended that salaries should be raised and urged the members to stand up for their just rights, recognising at the same time that their common well-being was inseparably connected with the welfare of the poor. The toast of "The Guests" was proposed by the President and was replied to by Sir Walter Foster, M.P., who pointed out that to secure the desired reforms it was necessary for the medical men concerned to combine and observed that the want of unity among the units of the profession must be remedied. Sir William Collins also responded to the toast and said that he looked forward to the Poor-law regulations being brought into line with the modern spirit of the local government of this country. Dr. H. R. Crocker was then called upon to reply to the toast and after he had done so, Mr. D B. Balding submitted the toast of "The President," which was suitably acknowledged.

VAGRANCY AND THE SPREAD OF INFECTIOUS DISEASE —The conference held in November last at Spring-gardens appointed a committee, consisting of representatives of county councils, county borough councils, and metropolitan authorities, to give practical effect to the resolutions adopted by the conference. The committee forwarded the resolutions adopted by the conference to the various associations of local authorities and resolutions endorsing the majority of the decisions of the conference have been received from the associations of municipal corporations and of metropolitan borough councils, and the Association of Poor-law Unions of England and Wales. The County Councils' Association has referred the resolutions to the various county councils but no decision has as yet been arrived at by the association. On June 22nd a deputation, consisting of the committee of the conference and representatives from the Association of Poor-law Unions, was received by the President of the Local Government Board at the House of Commons. The deputation was introduced by Sir Walter Plummer, M.P. Alderman H. W. Newton of Newcastle-upon-Tyne submitted the resolutions adopted by the conference and those adopted by the associations already mentioned. He urged that legislation to give effect to the views of the conference should be promoted at an early date. The Mayor of Wandsworth (the Rev. J. H. Anderson) spoke on behalf of the metropolitan authorities and Dr. J. Milson Rhodes on behalf of the county councils. At the conclusion of the latter's remarks Mr. Gerald Balfour, who gave the deputation a most sympathetic reception, invited all those present to express their views on the question.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

THE election of Fellows to fill the vacancies in the Council of the College under the new regulations was held at the College, Lincoln's Inn Fields, on Thursday, July 6th, between 2 P M. and 4 P.M.

The result of the voting was as follows —

	Votes	Plumpers.
MR. EDMUND OWEN	512	22
MR GOLDING-BIRD	480	73
MR. R. J GODLEE	471	6
MR. W. HARRISON CRIPPS	373	87
MR. ANDREW CLARK	315	16
MR. W. BRUCE CLARKE	66	2

Mr. Owen, Mr. Golding-Bird, Mr Godlee, and Mr. Harrison Cripps were elected members of Council.

It will be remembered that Mr. Bruce Clarke withdrew his candidature.

Mr. Willmott Evans and Mr H. J. Price of Maldon acted as scrutineers.

760 Fellows voted by post and 12 voted personally, 3 proxies arrived too late and 3 voting papers were spoiled.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 28TH.

Experiments upon Animals.

Mr. MACDONA asked the Secretary of State for the Home Department whether he was aware of the increase in the number of experiments by vivisectors upon animals this year over last year, the numbers being 32,562 in 1905, as against 19,084 in 1904, being a total increase of 13,478, and whether, in view of this increase, he would take steps to reduce this number.—Mr. AKERS DOUGLAS answered I am of course aware of the increase pointed out by the honourable Member. The particulars on pages four and five of the Annual Return show that this increase is almost wholly in the experiments included in Table IV. (B), i.e., experiments of the nature of simple inoculations or hypodermic injections and a very large proportion of those experiments were performed on behalf of official bodies. The progressive rise in the total number of experiments in recent years has been due almost entirely to the constantly increasing importance attached by the public and by public authorities to experiments upon animals as a means of obtaining the knowledge required for the diagnosis of disease or for the prevention [illegible] It is not for me to take any action in [illegible] uties under the statute are confined to seeing [illegible] ments are conducted in conformity with the provisions of the Act

Tuberculosis in Man and Animals.

Mr. FIELD asked the President of the Local Government Board whether he could state when the report of the Bovine Tuberculosis Commission would be issued, whether his attention had been called to the statement of Dr. Koch respecting the interim report as to the absence of evidence to prove that man can be infected by animal tuberculosis in any but the very slightest degree, and whether, in view of this pronouncement, the Government would support the Tuberculosis Compensation Bill.—Mr. GERALD BALFOUR replied As I stated in my reply to the honourable Member for the eastern division of Northants on June 9th I understand that the Royal Commission hopes to issue a further interim report towards the end of the present year but that it is not possible to say at present when the final report will be issued. My attention has been drawn to the statement of Dr. Koch referred to. I sympathise with the object of the Bill mentioned in the last part of the question but I am afraid I cannot give any promise with regard to it.

THURSDAY, JUNE 29TH.

The Medical Register.

Mr WEIR asked the Secretary of State for the Home Department whether, having regard to the fact that the General Medical Council stated that during the last ten years 20 names had been struck off the Medical Register for infamous conduct in a professional respect, and that of this number four were removed on charges of adultery, he would state how many names had been removed on this charge during the current year.—Mr. AKERS DOUGLAS replied. The answer to the question is three. I must add that the Medical Register is a matter with which I have no concern and that any other information which the honourable Member may desire would no doubt be furnished to him by the General Medical Council if he makes application to the Registrar.

Blood Poisoning in an Irish Infirmary.

Mr. SAMUEL YOUNG asked the Chief Secretary for Ireland whether, considering the number of deaths in the Cootehill workhouse in January, 1904, after medical operations from alleged blood poisoning, the Local Government Board had taken any steps to ascertain the cause of death in these cases; and whether, in view of the difference of opinion by local experts as to the cause of these deaths, and that the Local Government Board inspector reported that it was difficult to assign a direct and definite cause for the outbreak in this case, he would consider the advisability of ordering a sworn inquiry before the guardians were called upon to incur heavy expenditure for structural alterations.—Mr LONG replied The Board's medical inspector has already made minute investigation into the cause of this outbreak of blood poisoning. Though he was unable to assign the definite cause of the outbreak he was strongly inclined to the opinion of the union medical officer that the source of infection was in the wards of the infirmary. In the opinion of the Board a sworn inquiry would not be likely to throw further light on the matter.

Allegations in an Irish Case.

Mr. SAMUEL YOUNG further asked the Chief Secretary for Ireland whether he was aware that on or about June 20th, 1904, the medical officer of the Cootehill union, county Cavan, performed an operation on a patient called Fitzpatrick in the fever hospital after a local medical man who usually assisted at all such operations refused to administer ether because of the low condition of the patient, whether he was aware that the medical officer of the workhouse then called in a medical man from outside the Cootehill district, performed the operation, and the patient died a few hours after, whether the Local Government Board was informed of the facts and the cause of death in this case, and whether there was an inquest held or a sworn inquiry ordered.—Mr. LONG replied The Local Government Board is informed by the clerk of the union that the facts are substantially as stated. The local medical man referred to did not, however, refuse to administer ether, but asked to be excused as he was not in good health. The patient died on the day following the operation No complaint was made to the Board and no inquest or sworn inquiry was held The medical officer who performed the operation has the reputation of being a most careful and competent surgeon and the Board sees no reason to presume that there were any circumstances connected with the patient's death which require investigation.

Infant Mortality.

Mr HERBERT SAMUEL asked the President of the Local Government Board what was the death rate per 1000 births of infants under the age of 12 months in the urban and rural districts respectively of England and Wales —Mr. GERALD BALFOUR answered The best available information on this subject will be found on pages 73 and 74 of the Registrar General's Sixty sixth Annual Report which contains tables showing the infantile mortality (*a*) for a group of counties that are mainly urban, and (*b*) for a group of counties that are mainly rural in character. The following particulars are taken from these tables. Infantile mortality—Deaths under one year of age per 1000 births—urban counties average for 1898–1902, 165, 1903, 143, rural counties. average for 1898–1902, 126, 1903, 107.

MONDAY, JULY 3RD

Tuberculosis in Fowls.

Mr. MORRELL asked the President of the Board of Agriculture whether he had information to what extent this season tuberculosis was found in fowls, and whether he would cause inquiry to be made and information laid before the Commission on Tuberculosis with a view to ascertain whether that disease bore relation to that found in man and might be communicated to man in foods —Mr AILWYN FELLOWES answered We have no information to show that the disease in question is specially prevalent amongst poultry this season, but I will bring the suggestion of my honourable friend under the notice of the Royal Commission. I may add that we have prepared and issued a leaflet on the subject, with copies of which I shall be glad to supply him.

TUESDAY, JULY 4TH.

Insanitary Conditions and Fever.

Mr. WEIR asked the Lord Advocate whether he was aware that Dr. Cameron, the medical officer of health of the parish of Lochs, Island of Lewis, Ross-shire, stated in his report to the medical officer of health of the county that, being called upon to make inquiry in regard to two outbreaks of fever in the Balallan district, one of typhus and the other typhoid, he came to the conclusion that the outbreaks were due to the generally insanitary conditions prevalent; and whether, seeing that there were 108 pupils on the Balallan public school register, it was proposed to take any action to protect the lives of these children.—The LORD ADVOCATE said: I am aware that the outbreaks of fever referred to by the honourable Member are attributed to the insanitary conditions generally prevalent in the district which affect not only the children on the school register but the population at large. The matter engages the anxious consideration of the Secretary for Scotland and the Local Government Board who would be in a better position to remedy the evils complained of if the Congested Districts Amendment Bill now before the House became law.

SELECT COMMITTEE ON REGISTRATION OF NURSES.

The Select Committee of the House of Commons which is dealing with the subject of registration of nurses heard further evidence on June 27th. Mr. H. J. TENNANT presided.

Dr. ERNEST W. WHITE, professor of psychological medicine at King's College, London, chairman of the Parliamentary Committee of the Medico-Psychological Association of Great Britain and Ireland, and a member of the council of the Royal British Nurses Association, was the first witness. Examined by the Chairman he stated that the Medico-Psychological Association, which was an association of duly qualified persons interested in the treatment of the insane, had a system of registration. It granted certificates and it claimed for the holders of these certificates that they had attained a standard of efficiency and were of good moral character. They at least knew their work and the large majority of them possessed natural capacity for their work. Immense improvement had taken place in the nursing of the insane and tact, refinement, resource, and sympathy had replaced the ignorance, impatience, and brute force of former times. It was for that reason that he thought that mental nurses, male and female, should be eligible for any scheme of State registration of nurses that might be inaugurated.

The CHAIRMAN: What is the proportion of males and females amongst the 6500 persons who have passed your examination?

Witness: The registrar cannot give the precise figures to me but I should say about three-fifths of them were females.

The CHAIRMAN: You are a microcosm in yourselves of what it is suggested should be done for the whole country.

Witness: We think so.

In reply to Dr. C. F. HUTCHINSON, the witness stated that if State registration of nurses were carried out the register of his association might possibly become unnecessary. He would not go the length of saying that one year of the training of a mental nurse should be spent in a general hospital because there were excellent hospitals attached to some asylums where good training in sick nursing could be obtained.

Dr. G. E. SHUTTLEWOR
Workers' Association, then
he said that the expediency
qualified to attend upon cas
connexion with the general question of registration of nurses. As a rule hospital trained nurses had no experience of the special character required in mental cases. If registration were carried out, it would probably be necessary that hospital trained nurses and asylum trained nurses should appear in separate lists in the official register. Though the Asylum Workers' Association did not require any qualification for membership other than the recommendation of the medical superintendent for those in asylum service, it was the fact that about one-fourth of the members held the certificate of the Medico-Psychological Association, whilst others held certificates granted by their own asylums and a considerable number the first aid or nursing certificate of the St. John Nursing Association. It was important for the protection of the public that provision should be made for a class of private mental nurses in any scheme for the registration of nurses, because there were many unqualified or imperfectly qualified persons offering themselves as private mental nurses. The qualification for registration as a mental nurse should be at the least three years' experience in a recognised asylum where systematic training was given and the possession of the certificate in nursing of the
Medico-Psycholog certificate. The
Asylum Workers' ık and file of those
in the asylum se scheme for the
government of the nursing profession which included mental nursing. The witness, however, admitted the superior claims of the Medico-Psychological Association as an examining authority.

Mr. J. PATTEN MACDOUGALL, vice-president of the Local Government Board for Scotland, was the next witness. Examined by the Chairman, he said that there had been in existence in Scotland a register of Poor-law nurses since 1885. The origin of that register was due to the fact that the Board of Supervision, which was the predecessor of the Local Government Board for Scotland, was extremely anxious to get rid of pauper nursing in the poor houses in Scotland.

The CHAIRMAN: What you call pauper nursing was that the poor nursed each other.

Witness: That is generally what it amounted to. He went on to explain that the Scottish Local Government Board had no power to compel Poor-law authorities to abandon pauper nursing and untrained nursing. However the Board was able to offer inducements in this direction to Poor-law authorities owing to the flexible conditions under which the medical relief grant was distributed. It was thus enabled to make certain payments and allowances to Poor-law authorities in respect of the trained nurses whom they employed if those nurses were on the Board's list. The Board required that anyone admitted to registration should be "a trained sick nurse who should have been not less than two years in a public hospital, being a training school for nurses and maintaining a resident physician, and she must not be under 22 years of age nor over 45 when first registered."

The CHAIRMAN: The register is kept by the Board for the purpose of obtaining an efficient service of nursing for the poorhouse?

Witness: Yes, that is the object.

The CHAIRMAN: Have you found it effective from that point of view?

Witness: Yes. He proceeded to state that since 1885 there had been 773 names put upon the Local Government Board's register or an average of 36 per annum. In recent years the annual number of registrations had increased and in 1904–05 90 names were added to the register. At present 219 of the nurses so registered were in the employment of Poor-law authorities.

The committee then adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BIRD, RICHARD KINGSTON, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Acting Officer of Health for the shire of Arapiles, Victoria, Australia.

BROWN, ROBERT LEE, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Acting Officer of Health for the shire of Cranbourne, Victoria, Australia.

LAURIE, HENRY, M.D. Melb., has been appointed Honorary Assistant Physician at the Alfred Hospital, Victoria, Australia.

LEDINGHAM, J. C. G., M.A., B.Sc., M.B. Aberd., has been appointed Assistant Bacteriologist to the Serum Department, Lister Institute, Elstree.

MORRIS, L. N., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant House Surgeon at the Bristol General Hospital.

OLIVER, W., L.R.C.P., L.R.C.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Coxhoe District of the county of Durham.

PARRY, LLOYD DAVENPORT, L.R.C.S. Edin., has been appointed Government Medical Officer and Vaccinator at Picton, New South Wales, Australia.

PATON, E. PERCY, M.D. Lond., has been appointed Examiner in Anatomy to the Society of Apothecaries of London.

RICHARDSON, A. G., M.B., C.M. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Rhayader District of the county of Radnor.

RICHARDSON, A. W. CECIL, M.B. Lond., has been appointed Casualty House Surgeon at the Bristol General Hospital.

RICHMOND, G. E., M.D., B.S., B.Sc. Lond., D.P.H. Cantab., has been appointed by the London County Council Resident Medical Officer to the Rotherhithe Tunnel Works.

ROSE, JOHN STUART, M.B., Ch.B. Aberd., D.P.H., has been appointed Assistant Medical Officer of Health of Penang.

SHEPPARD, A. L., M.B., has been appointed Casualty Officer at the Bristol Royal Infirmary.

SHORT, ARTHUR RENDLE, M.D., B.S., B.Sc. Lond., has been appointed House Physician to the Bristol General Hospital.

SYMES, J. O., M.D. Lond., has been appointed Physician to Clifton College, Bristol.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ARMY MEDICAL SERVICE.—40 Commissions in the Royal Army Medical Corps.

AYR COUNTY HOSPITAL.—Resident House Surgeon. Salary £70 per annum, with residence, board, and washing.

BRADFORD UNION HOSPITAL AND WORKHOUSE.—Resident Assistant Medical Officer, unmarried. Salary £100, with rations, apartments, and washing.

BRIGHTON, ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke-road.—House Surgeon. Salary £80, with board, lodging, and washing.

CAIRO, SCHOOL OF MEDICINE.—Assistant to the Professor of Anatomy. Also Assistant to the Professor of Pathology. Salary in each case is £E320 per annum.

CHARING CROSS HOSPITAL.—Assistant Surgeon.

DERBY, DERBYSHIRE ROYAL INFIRMARY.—Assistant House Surgeon for six months. Salary £30, with board, residence, and washing.

DORCHESTER, DORSET COUNTY HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

HAMMERSMITH INFIRMARY AND WORKHOUSE, Ducane-road, Wormwood Scrubs, W.—Medical Superintendent and Medical Officer. Salary £300 per annum, with house, coals, light, and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident Medical Officer. Salary £200 per annum, with board and residence.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon, unmarried. Also House Physician, unmarried. Also Assistant Casualty Medical Officer, unmarried. All three appointments for six months. Salaries £20, with board and residence.

HOSPITAL FOR WOMEN, Soho-square, W.—Registrar. Honorarium 25 guineas.

HULL ROYAL INFIRMARY.—Casualty House Surgeon... Salary £50 per annum, with board and lodging. Also Locum Tenens.

KENT AND CANTERBURY HOSPITAL.—Honorary Physician.

LEICESTER, BOROUGH OF, EDUCATION COMMITTEE.—Medical Officer. Remuneration £400 per annum, rising to £450.

MANCHESTER, VICTORIA UNIVERSITY.—*Junior Demonstrator* in Physiology. Salary £100, rising to £150 per annum.

NORFOLK AND NORWICH HOSPITAL.—Assistant House Surgeon for six months. Honorarium £20, with board, lodging, and washing.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Second Honorary Anæsthetist.

ORKNEY, PAPA WESTRY PARISH COUNCIL.—Lady Medical Officer and Public Vaccinator. Salary £75, with fees, house, and garden.

READING, ROYAL BERKSHIRE HOSPITAL.—Secretary and House Governor. Salary £200 per annum, with residence.

ST. MARY'S HOSPITAL, Paddington, W.—Honorary Anæsthetists.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—*Junior House* Surgeon. Salary £50 per annum, with rooms, board, and washing.

SOUTH UIST (SOUTHERN DIVISION).—Medical Officer. Salary £77 10s.

STOKE-UPON-TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill.—Senior House Surgeon. Salary £100 *per annum, with apartments*, board, and washing.

VENTNOR, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION.—Senior Resident Medical Officer, unmarried. Salary £200 per annum, with board and lodging.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Physician for six months. Honorarium of £25, with board and lodging.

WAKEFIELD, WEST RIDING ASYLUM.—Locum Tenens for six weeks. Terms £3 3s. per week, residence, board, &c.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the *Factory* and Workshop Act at Wimbledon, in the county of Surrey.

Births, Marriages, and Deaths.

BIRTHS.

CAMPS.—On June 28th, at Udney-park, Teddington, Middlesex, the wife of Percy W. L. Camps, M.B., B.S., F.R.C.S., of a son.

JONES.—On July 2nd, at Claybury, Woodford Bridge, Essex, the wife of Robert Jones, M.D., of a daughter.

LEANING.—On June 22nd, at Rusthall-avenue, Bedford-park, the wife of R. Craske Leaning, M.B., B.S., M.R.C.S., of a son.

ROBINSON.—On June 29th, at Marine-terrace, Waterloo, Liverpool, the wife of G. Burton Robinson, M.B., M.R.C.S., L.R.C.P., of a daughter.

MARRIAGE.

WEDDERBURN—BANKIER.—On June 28th, at St. Paul's Church, Adlington, Lancashire, Laurence Craigie Maclagan Wedderburn, M.B., Ch.B., to Inez Amy, second daughter of W. H. Bankier, Flushing, New York, U.S.A.

DEATHS.

METCALFE.—On July 3rd, at Clifton-gardens, W., Edmund Metcalfe, F.R.C.S., in his 66th year.

SMITH.—On July 5th, at Orleans House, Regent's Park-road, N.W., Cyrus Walter Smith, L.R.C.P. Lond., M.R.C.S., the beloved and only surviving son of Walter Smith, M.D., M.R.C.P. Edin., and Susan Smith of above address, aged 32 years. Interment at Nunhead Cemetery on Tuesday, 11th inst.

WALES.—On June 27th, at Holywood, co. Down, George Frederick Wales, M.D. Aberd., F.R.C.S. Edin.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

SOME "MOTOR" NOTES FOR MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—In answer to many requests from professional friends afflicted with incipient motor fever I propose, with your permission, to reply to the many letters I have received on the subject through the medium of THE LANCET. I believe the following remarks will cover the various queries I have received. I bought my car in September, 1904, it being my fourth venture in automobiles. The car (Wolseley 6 h.p.), a two-seater, has a single horizontal engine, transmitting its power by a chain to the gear-box and from there by another chain to a live axle, to the extremity of which the driving-wheels are keyed. The engine is certainly the best I have come across. The exhaust valve-spring is a laminated one. I have had two of these break. I believe a spiral spring is less likely to fracture, but against this is the fact that they are more troublesome to replace. On my other cars, two Benz and one Brown, where these springs were of the spiral kind, I was lucky enough not to have any such trouble. A shield is fitted under the engine; this is a great protection, keeping the machinery free from mud and dust, but it has its inconveniences as it must be removed in order to replace a broken exhaust spring and as I can say from experience this is a trouble to do on the road. The seat of the exhaust spring is the lower part of the combustion chamber; it would, I consider, be better if the seat was removeable, as in the case of the inlet valve, which is easily taken out. The crank is solid and the bearings are well lubricated by sight feed lubricators. The pump is gear driven and the radiators keep the circulating water fairly cool. Convenient cocks are fitted to drain off the water in frosty weather. The carburetter is of the spray variety and acts well. The gear box is suspended from the frame by two bolts by which, too, the distance of the gear box from the fly wheel can be altered and thus the tension of the chain between these parts kept constant. The bolts originally fitted were five-sixteenths of an inch and were apt to break. On two occasions this occurred to me. I believe the makers now get stronger ones.

The clutch.—This part of the car has given me a good bit of trouble. It consists of a pan into which a leather covered cone fits, the power coming by a chain from the fly wheel to the pan. A spring keeping it pressed against the male portion by means of a pedal working a fo-k the female portion can be withdrawn and the engine thus thrown out of gear. The diameter of the pan is small and a medical man's work, of course, means many stoppages with resulting friction between the two surfaces. On three occasions I have been stuck up by a slipping clutch. Once when taking a patient to see a specialist in town the leather fired and we stayed for over an hour on Vauxhall Bridge before it would grip. I certainly had less trouble with the old-fashioned but now discarded belt transmission with a loose and a keyed pulley as fitted on the old 4½-h.p. Benz. Probably a larger diameter clutch would be more satisfactory.

The brakes.—The hand brake consists of two bands working on drums on the driving wheels and are actuated by a side lever and a wire cable. This cable is apt to break at the point where it bends round the lever. This once happpened to me on a hill when the clutch was slipping. The experience was thrilling but luckily without disaster. My life not being insured I substituted rods for the cable, which have the additional advantage of making certain that the bands are absolutely free of the drums when off. The foot-brake, which also works a throttle, has been a source of anxiety, as when it is supposed to be off it still bears on the drum on the live axle, thus causing waste of power. When I took delivery of the car I found this drum so hot that I could not bear my hand on it, and if it is adjusted so as not to bear there is not room to bring the pedal down sufficiently low to make it act when required. Seemingly, the makers have not yet improved this defect, as on a new car I saw last week the drum after a run of only seven miles was very hot.

Ignition is of the ordinary high-tension variety, the coil being worked by a four-volt accumulator. A little attention that the connexions are clean and the commutator working freely saves much trouble and may obviate interesting a street crowd by unearthly noises due to missfires or, what is even worse, a breakdown.

Excluding the defects mentioned I believe the car to be well-suited for a medical man's work. Certainly it is a good hill climber, but the brakes and clutch could be improved with advantage.

Tyres.—Dunlop pneumatic were fitted on my car and seem to wear well. In addition I had Trosse non-skids on the driving wheels, but after a short time these bands became loose in places and present the appearance of having sebaceous cysts where the air has got in between the leathern band and outer cover.

I am, Sirs, yours faithfully,
CHARLES T. W. HIRSCH, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A.,
Public Vaccinator and Police Surgeon, Woolwich; late
Colonial Medical Service, Fiji.

Woolwich, June 28th, 1905.

ATTENDANCE ON THE CHILDREN OF MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—I should be glad of information on the following points. Are the children of a deceased medical man always entitled to free medical attendance during their lifetime; if not, how far does this custom extend? Is it usual to attend free a patient in the position of a householder or an adult merely because his father was a doctor?

I am, Sirs, yours faithfully,
July 3rd, 1905. INQUIRER.

*** No definite rule can be laid down. Whether free attendance be given or not should, we think, depend upon the pecuniary circumstances of the patient. We do not consider that a patient is necessarily to be attended free because his father was a medical man, and certainly when the son of a medical man is the master of a house and well able to pay all the other claims upon him he should pay his medical adviser.—ED. L.

RED RUBBER.

WITH regard to the suggestion that red rubber may be a source of antimonial poisoning Aerators, Limited, of Angel-road, Edmonton, write: "There are only two washers in the 'sparklet' syphon head—one which is liable to come in contact with the water—viz., that on the bottle neck, which is purposely made in block rubber; a second which receives the neck of the bulb and makes the joint on piercing the latter—this is of red rubber, but no water comes in contact with this washer and no particles of this washer can get into the interior of the bottle." We find that this description of the sparklet bottle is correct in every particular.

Referring to the same subject Messrs. Camwal, Limited, of 112, Pembroke-street, Caledonian-road, N., state that most syphons do not contain red rubber and if they did it would be next to impossible for the rubber to get into the water. With regard to bottles, so far as mineral waters are concerned they have always been of opinion that the old-fashioned cork is the best stopper.

Messrs. Type and King, manufacturers of golden sulphide of antimony, 16, Mincing-lane, London, E.C., doubt whether the acid carbonates of soda and potash or the organic acids would have any solvent action on red antimony and state that the maximum quantity of antimony ever employed in rubber is about one-sixth of the weight of the rubber.

These remarks are in agreement with the results of analysis and experiments which we recorded in an annotation in THE LANCET of June 24th, p. 1736, to which we may refer our correspondents.

AN INTERESTING CASE OF RETENTION TO THE AMOUNT OF A GALLON.

To the Editors of THE LANCET.

SIRS,—On June 29th I was urgently sent for to see a woman, aged 25 years, a multipara. She was in great pain. The abdomen was fully distended. Absolute dulness and vibratory tremor were well marked all over the abdomen. There were bulging of the perineum and protrusion of the posterior vaginal wall. She assured me that she had passed plenty of urine. There was a history of five months pregnancy. With slight difficulty I introduced the catheter and drew off *four quarts* of urine. On vaginal examination I found an enlarged uterus retroverted and fixed; this I reduced after placing the patient in the genu-pectoral position. The interest in this case is the capacity for practically unlimited distension of the bladder. The amount drawn off was carefully verified by measuring in an imperial half-pint measure (stamped). This distension of the abdomen had only arisen within the last four or five days. The patient has since the replacement of the uterus voluntarily passed two quarts at the time, and there appears to be no disturbance in the gestation.—I am, Sirs, yours faithfully,
Mile End-road, E., July 3rd, 1905. M. CURSHAM CORNER.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—May I through the medium of your journal thank the many correspondents who answered my letter in THE LANCET of July 1st? There have been too many to answer personally by letter so I take this means of doing so. I am, Sirs, yours faithfully,
BERTRAM ADDENBROOKE.
Kidderminster, July 4th, 1905.

SYMPTOMS FOLLOWING THE INHALATION OF POLLANTIN.

To the Editors of THE LANCET.

SIRS,—A patient of mine purchased a tube of pollantin at a chemist's shop and started self-medication. The following are the notes of the case, which I hope you will publish in order to elicit further communications and to see if similar results have been observed by others. Or may we conclude that the symptoms in my patient could possibly be accounted for otherwise? A middle-aged gentleman had suffered for years from hay fever. He had never had attacks of giddiness. Hearing of the benefit a friend had obtained by using pollantin he determined to try it. On June 12th he started at 7 P.M. inhaling up his nostrils the quantity advised in the prospectus. At 10.30 P.M. he took a second inhalation and retired to bed. Next morning at 5.30 he awoke feeling very giddy and noticing a buzzing in the ears. The least movement of the head caused vertigo. The hay fever was checked, he said, but the feeling of giddiness was "horrible." He also noticed a dull, curious, aching feeling at the back of the head. Making an effort he dressed and later went to London. The symptoms persisted on and off all day. Coming home at 6 P.M. he stooped to pat his dog and then the vertigo became intense and he vomited. I saw him at 9 P.M.; he was on his back in bed, afraid to turn his head, and was complaining greatly of pain in the occipital region. His face looked pinched and cyanosed; his pulse was 48. The feeling of sickness passed off gradually. On the next morning I found that he had had a good night; the tinnitus had gone but he was still unable to move his head on account of the vertigo thus caused. The pulse was 54. His condition remained the same all day. Next morning he was decidedly better, able to move his head, but not able to get up because of the giddiness. The pulse was 60. Improvement was then gradual, and three days after the onset of the attack he was able to sit out of bed. He now appears to be convalescent and has had no return of the hay fever.

I am, Sirs, yours faithfully,
South Croydon, June 26th, 1905. A. PERCY ALLAN, M.D. Lond.

THE FARMHOUSE TREATMENT OF TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—I shall be glad of information from your readers as to the existence of hillside, or seaside, or country cottages or farmhouses where tuberculous patients are treated under the care of a resident nurse with occasional visits from the medical man. How does such treatment compare with proper sanatorium treatment? I should like to be put in touch with any such places and the individuals who are in charge of them. What is likely to be the comparative cost of their working? This, of course, I would like to obtain from those responsible for their maintenance. Sanatorium figures I have, as they are abundantly to be got. It is suggested locally to endeavour to deal with tuberculous cases by taking cottages or small houses in the district and running them on the lines suggested by my letter.

I am, Sirs, yours faithfully,
Rochdale, June 21st, 1905. WILLIAM STANWELL, M.R.C.S. Eng.

THE COST OF LIVING IN WEST AFRICA.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if some medical man lately returned from the West African gold-mines would tell me the cost of living per week inclusive and how long it would take to travel from the coast to the gold-fields. I am, Sirs, yours faithfully,
June 29th, 1905. ST. GEORGE QUEELY, L.R.C.P. Irel.

OLD BOOKS.

M.B. writes:—"If 'R. D.' would instruct the Church Army, Edgware-road, to call for his books they would be taken away gladly, as the Church Army can dispose of them, but the society will not purchase or give anything for them."

◆

Æternum Nefas.—Our correspondent, writing above a pseudonym which shows him to be completely mistaken as to the circumstances, should submit his questions to a medical man. We cannot break our rule of never recommending a practitioner by name, specialist or otherwise, but we may say that any medical man will be able to give him the assistance that he wants.

C. A. M.—We do not think that it is necessary to read special monographs. Our correspondent might read Foster's, *Physiology* in addition to the work which he mentions and we advise him to consult the article entitled "The Students' Library" which appeared in THE LANCET of Sept. 3rd, 1904.

G.P.—Why not apply directly to the principal? It is notorious that medical opinions differ, and there is really not yet enough evidence to warrant a dogmatic answer.

P. Z. Giuseppe.—We regret that we cannot give the information but any medical publisher, certainly any foreign medical publisher, would be able to do so.

Ars.—In our opinion the conditions mentioned by our correspondent should be included.

ERRATUM.—In Dr. H. G. Adamson's paper on the Treatment of Ringworm of the Scalp by Means of the X Rays, published in THE LANCET of June 24th, "four" milliampères on p. 1716, col. i., line 31, should be *0·4* milliampère.

Central London Throat and Ear (2 P.M.).

SATURDAY (15th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.)

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (11th).—SOCIETY FOR THE STUDY OF INEBRIETY (Rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W.).—3.30 P.M. Council Meeting. 4 P.M. Discussion on the Psychology of the Inebriate (opened by Dr. T. C. Shaw).

WEDNESDAY (12th).—THERAPEUTICAL SOCIETY (Royal Botanic Society's Gardens, Regent's Park.)—Garden Meeting to view the Medicinal and Other Plants.

DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—5.15 P.M. Meeting.

THURSDAY (13th).—BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Dr. C. Maunsell: (1) A Case of Endothelioma Uteri (illustrated by drawings and microphotographs). (2) An Improved Method of Ventrofixation of the Uterus (illustrated).—Dr. H. Macnaughton-Jones· (1) Note on Cyllin as a Post-operative Antiseptic. (2) Note on a Case of Post-operative Parotitis; (3) Note on a Case of Urethral Cyst.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (10th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr T. C. Fox: Clinique. (Skin.) 5.15 P.M. Mr. T. Walker: Some Recent Methods of Diagnosis in Urinary Surgery.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Robinson: Gynæcology.

TUESDAY (11th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. C. T. Williams: Clinique. (Medical.) 5 15 P.M. Dr. L. Williams: The Therapeutics of Some Common Ailments.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. S. Taylor: Cerebral Hæmorrhage.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M. Mr. M. Gunn: Optic Neuritis.

WEDNESDAY (12th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Berry: Clinique. (Surgical.) 5.15 P.M. Dr. J. Fawcett: Cancer of the Stomach.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Robert Jones: Prognosis in Mental Disease.

THURSDAY (13th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.) 5 15 P.M. Dr. D. Sommerville: Errors of Digestion in Relation to Disease.

POST GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.) 5 P.M. Mr. Baldwin: Practical Surgery.

HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Lecture:—Mr Ballance: Demonstration on Surgical Cases.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7, Fitzroy-square, W.).—5 P.M. Lecture:—Mr. H. Barwell: The Diagnosis of Tuberculous Laryngitis in its Early Stage. Post-Graduate Course.)

FRIDAY (14th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. H. W. Dodd: Clinique. (Eye.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. S. Taylor: Diagnosis in Lesions of the Spinal Cord.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1905, which was completed with the issue of June 24th, and the Title-page to the Volume, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1905 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

During the week marked copies of the following newspapers have been received:- *Western Mail (Cardiff), Herefordshire Mercury, St. Helens News and Advertiser, Westminster Hospital Gazette, Nursing Times, Mercy and Truth, Dublin Weekly Times, Liverpool Post and Mercury, Westminster Gazette, Yorkshire Mercury, Manchester Chronicle, Daily Chronicle, Irish Times, Morning Leader, Surrey Advertiser, Literary Digest (New York), Scientific American, Daily News, Australasian Medical Gazette, &c.*

ATTENDANCE ON THE CHILDREN OF MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—I should be glad of information on the following points. Are the children of a deceased medical man always entitled to free medical attendance during their lifetime; if not, how far does this custom extend? Is it usual to attend free a patient in the position of a householder or an adult merely because his father was a doctor?

I am, Sirs, yours faithfully,

July 3rd, 1905. INQUIRER.

*** No definite rule can be laid down. Whether free attendance be given or not should, we think, depend upon the pecuniary circumstances of the patient. We do not consider that a patient is necessarily to be attended free because his father was a medical man, and certainly when the son of a medical man is the master of a house and well able to pay all the other claims upon him he should pay his medical adviser.—ED. L.

RED RUBBER.

WITH regard to the suggestion that red rubber may be a source of antimonial poisoning Aerators, Limited, of Angel-road, Edmonton, write: "There are only two washers in the 'sparklet' syphon head—one which is liable to come in contact with the water—viz., that on the bottle neck, which is purposely made in block rubber; a second which receives the neck of the bulb and makes the joint on piercing the latter—this is of red rubber, but no water comes in contact with this washer and no particles of this washer can get into the interior of the bottle." We find that this description of the sparklet bottle is correct in every particular.

Referring to the same subject Messrs. Camwal, Limited, of 112, Pembroke-street, Caledonian-road, N., state that most syphons do not contain red rubber and if they did it would be next to impossible for the rubber to get into the water. With regard to bottles, so far as mineral waters are concerned they have always been of opinion that the old-fashioned cork is the best stopper.

Messrs. Type and King, manufacturers of golden sulphide of antimony, 16, Mincing-lane, London, E.C., doubt whether the acid carbonates of soda and potash or the organic acids would have any solvent action on red antimony and state that the maximum quantity of antimony ever employed in rubber is about one-sixth of the weight of the rubber.

These remarks are in agreement with the results of analysis and experiments which we recorded in an annotation in THE LANCET of June 24th, p. 1736, to which we may refer our correspondents.

AN INTERESTING CASE OF RETENTION TO THE AMOUNT OF A GALLON.

To the Editors of THE LANCET.

SIRS,—On June 29th I was urgently sent for to see a woman, aged 25 years, a multipara. She was in great pain. The abdomen was fully distended. Absolute dulness and vibratory tremor were well marked all over the abdomen. There were bulging of the perineum and protrusion of the posterior vaginal wall. She assured me that she had passed plenty of urine. There was a history of five months pregnancy. With slight difficulty I introduced the catheter and drew off *four quarts* of urine. On vaginal examination I found an enlarged uterus retroverted and fixed; this I reduced after placing the patient in the genu-pectoral position. The interest in this case is the capacity for practically unlimited distension of the bladder. The amount drawn off was carefully verified by measuring in an imperial half-pint measure (stamped). This distension of the abdomen had only arisen within the last four or five days. The patient has since the replacement of the uterus voluntarily passed two quarts at the time, and there appears to be no disturbance in the gestation.—I am, Sirs, yours faithfully,

Mile End-road, E., July 3rd, 1905. M. CURSHAM CORNER.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—May I through the medium of your journal thank the many correspondents who answered my letter in THE LANCET of July 1st? There have been too many to answer personally by letter so I take this means of doing so. I am, Sirs, yours faithfully,

BERTRAM ADDENBROOKE.

Kidderminster, July 4th, 1905.

SYMPTOMS FOLLOWING THE INHALATION OF POLLANTIN.

To the Editors of THE LANCET.

SIRS,—A patient of mine purchased a tube of pollantin at a chemist's shop and started self-medication. The following are the notes of the case, which I hope you will publish in order to elicit further communications and to see if similar results have been observed by others. Or may we conclude that the symptoms in my patient could possibly be accounted for otherwise? A middle-aged gentleman had suffered for years from hay fever. He had never had attacks of giddiness. Hearing of the benefit a friend had obtained by using pollantin he determined to try it. On June 12th he started at 7 P.M. inhaling up his nostrils the quantity advised in the prospectus. At 10.30 P.M. he took a second inhalation and retired to bed. Next morning at 5.30 he awoke feeling very giddy and noticing a buzzing in the ears. The least movement of the head caused vertigo. The hay fever was checked, he said, but the feeling of giddiness was "horrible." He also noticed a dull, curious, aching feeling at the back of the head. Making an effort he dressed and later went to London. The symptoms persisted on and off all day. Coming home at 6 P.M. he stooped to pat his dog and then the vertigo became intense and he vomited. I saw him at 9 P.M.; he was on his back in bed, afraid to turn his head, and was complaining greatly of pain in the occipital region. His face looked pinched and cyanosed; his pulse was 48. The feeling of sickness passed off gradually. On the next morning I found that he had had a good night; the tinnitus had gone but he was still unable to move his head on account of the vertigo thus caused. The pulse was 54. His condition remained the same all day. Next morning he was decidedly better, able to move his head, but not able to get up because of the giddiness. The pulse was 60. Improvement was then gradual, and three days after the onset of the attack he was able to sit out of bed. He now appears to be convalescent and has had no return of the hay fever.

I am, Sirs, yours faithfully,

South Croydon, June 26th, 1905. A. PERCY ALLAN, M.D. Lond.

THE FARMHOUSE TREATMENT OF TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—I shall be glad of information from your readers as to the existence of hillside, or seaside, or country cottages or farmhouses where tuberculous patients are treated under the care of a resident nurse with occasional visits from the medical man. How does such treatment compare with proper sanatorium treatment? I should like to be put in touch with any such places and the individuals who are in charge of them. What is likely to be the comparative cost of their working? This, of course, I would like to obtain from those responsible for their maintenance. Sanatorium figures I have, as they are abundantly to be got. It is suggested locally to endeavour to deal with tuberculous cases by taking cottages or small houses in the district and running them on the lines suggested by my letter.

I am, Sirs, yours faithfully,

Rochdale, June 21st, 1905. WILLIAM STANWELL, M.R.C.S. Eng.

THE COST OF LIVING IN WEST AFRICA.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if some medical man lately returned from the West African gold-mines would tell me the cost of living per week inclusive and how long it would take to travel from the coast to the gold-fields. I am, Sirs, yours faithfully,

June 29th, 1905. ST. GEORGE QUEELY, L.R.C.P. Irel.

OLD BOOKS.

M.B. writes:—"If 'R. D.' would instruct the Church Army, Edgware-road, to call for his books they would be taken away gladly, as the Church Army can dispose of them, but the society will not purchase or give anything for them."

◆

Æternum Nefas.—Our correspondent, writing above a pseudonym which shows him to be completely mistaken as to the circumstances, should submit his questions to a medical man. We cannot break our rule of never recommending a practitioner by name, specialist or otherwise, but we may say that any medical man will be able to give him the assistance that he wants.

C. A. M.—We do not think that it is necessary to read special monographs. Our correspondent might read Foster's Physiology in addition to the work which he mentions and we advise him to consult the article entitled "The Students' Library" which appeared in THE LANCET of Sept. 3rd, 1904.

G.P.—Why not apply directly to the principal? It is notorious that medical opinions differ, and there is really not yet enough evidence to warrant a dogmatic answer.

P. Z. Giuseppe.—We regret that we cannot give the information but any medical publisher, certainly any foreign medical publisher, would be able to do so.

Ars.—In our opinion the conditions mentioned by our correspondent should be included.

ERRATUM.—In Dr. H. G. Adamson's paper on the Treatment of Ringworm of the Scalp by Means of the X Rays, published in THE LANCET of June 24th, "four" milliampères on p. 1716, col. i., line 31, should be *0·4* milliampère.

METEOROLOGICAL READINGS.

A Lecture

ON

TRACHEAL INJECTION: ITS SIMPLIFICATION AND ITS USE IN PULMONARY TUBERCULOSIS.

Delivered in English at the Hôtel Dieu in Paris on May 12th, 1905,

BY DR. MENDEL,

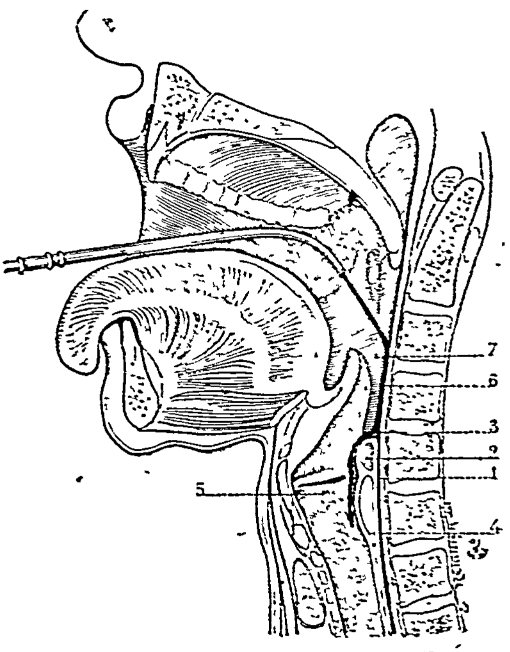
ANCIEN INTERNE DES HOPITAUX DE PARIS.

GENTLEMEN,—I wish to bring to your notice in a few words a therapeutic method which may be conveniently designated tracheal injection. It is not entirely new, as it was first practised in 1887, but it is, nevertheless, comparatively new, for it is even now nearly unknown to medical men in general. The injection of medicated liquids into the air passages was originated by Dr. Albert Jobson Beehag of Edinburgh and was also employed nearly at the same time by a German, Dr. Rosenberg of Berlin. The two were laryngologists and they performed this little operation by introducing the tube of the syringe into the larynx under the guidance of the laryngoscopic mirror. In this way they injected some drops of olive oil containing menthol: their aim was to diminish the pain caused by tuberculous laryngitis, but they were soon able to see that this injection, repeated every day, had also good results on the cough, the expectoration, and the respiration of the consumptive patient, and they advised the use of this method in pulmonary tuberculosis without laryngitis. It was accordingly employed by a few practitioners in different countries who all declared that they were very satisfied with it. The method, however, attracted little attention and remained almost entirely unknown except to the laryngologists, some of whom employed it in rare cases.

There were two principal reasons for this want of success. In the first place the injections were not easy to give, being in reality an endolaryngeal operation which could only be performed by a specially trained laryngologist. Moreover, as laryngologists do not usually treat pulmonary tuberculosis this therapeutic method was hardly ever used in the cases where it would have been most beneficial. The second cause of the non-success of this method was what might be called the prejudice against manipulative interference with the trachea. In fact, physiologists and medical men believed that the laryngo-tracheal tube was extremely sensitive and intolerant of foreign bodies and that injecting anything into it must necessarily produce coughing and suffocation. Here it is interesting to remark that laryngological practice confirmed this error, as the laryngologists injected into the air passages irritating liquids, such as menthol and creasote, which almost always made the patient cough violently, and they attributed to tracheal sensibility an effect which was really caused by the irritant properties of the medicines employed. I will give you two instances of this error of the laryngologists. A very distinguished laryngologist said to me some time ago, "At my hospital when I make one of my pupils give a tracheal injection I need not look at the operation. If I hear the patient coughing I think that the injection has been correctly performed; if not, the liquid has been wrongly injected and finally swallowed by the patient." This laryngologist was kind enough to be present at one of my demonstrations and was able to see that if the patient coughs after an injection the reason is that the liquid injected is irritating, and that after a non-irritating injection (pure olive oil or weak medicated solutions) the patient never coughs. Another well-known laryngologist told me that he never performed any tracheal injections, as he feared making the patient cough and choke.

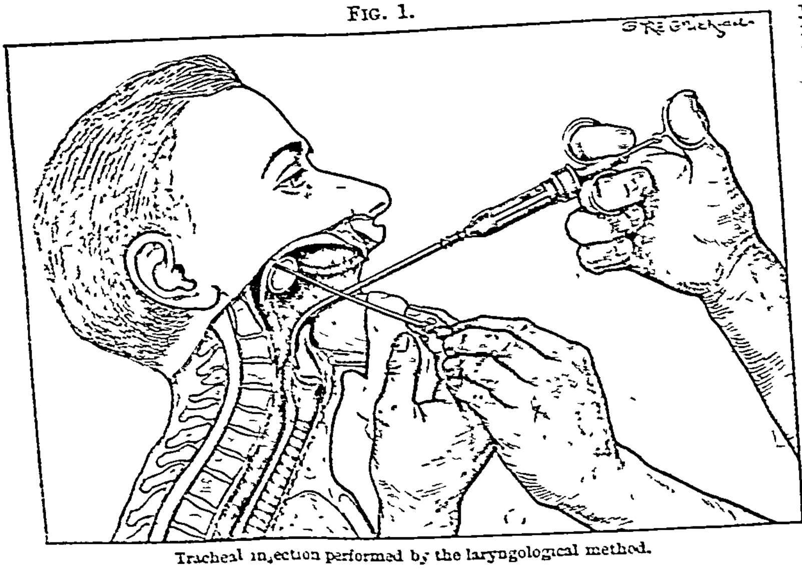
Such were the reasons which have hitherto caused tracheal injection to remain unknown to, and unemployed by, medical men, but the case is quite altered now, for after many researches and experiments I have proved (1) that the manipulations required for tracheal injection can be sufficiently simplified to be performed by any medical practitioner without any special laryngological training; and (2) that the introduction of non-irritating liquids into the air passages never causes any reflex, any coughing, or any suffocation. I have been able to simplify the technique of tracheal injection in accordance with the following observation. If the tongue of the patient is protruded and held outside the mouth, and

FIG. 2.



1. Laryngeal part of the pharynx. 2. Posterior wall of the larynx. 3. True origin of the œsophageal tube. 4. Anatomical origin of the œsophagus. 5. Cavity of the larynx. 6. Posterior wall of the pharynx. 7. Lateral wall of the pharynx.

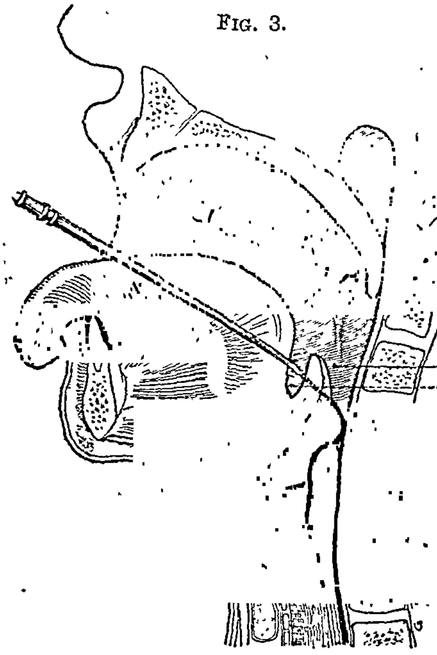
FIG. 1.



Tracheal injection performed by the laryngological method.

if he at the same time refrains from swallowing, the pharynx forms a funnel in which the only inferior outlet is the glottis, for the orifice of the œsophageal tube is closed except during the act of swallowing, so that a small quantity of liquid projected against the wall of the pharynx runs down into the air passages. The experiment is represented in Fig. 2. The experiment will also succeed if the liquid is projected against the lateral wall of the pharynx, as represented in Fig. 3, in which the injection after having been forcibly projected against the inferior part of the lateral wall of the pharynx is shown passing round to reach the posterior wall, whence it runs down into the larynx.

FIG. 3.



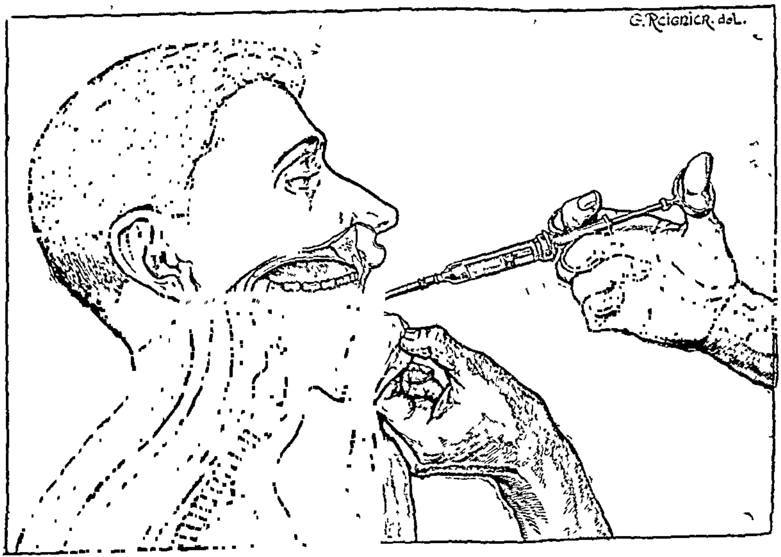
1. Laryngeal part of the pharynx. 2. Posterior wall of the larynx. 3. True origin of the œsophageal tube. 4. Anatomical origin of the œsophagus. 5. Cavity of the larynx. 6. Glosso-epiglottic groove. 7. Posterior wall of the pharynx. 8. Lateral wall of the pharynx.

Guided by these experiments I have devised two modes of injecting. The first method, called the medial method, is a repetition of the first experiment; it is the less used and the less convenient of the two. I therefore prefer describing the second or lateral method, which is the most convenient and which is always employed unless there be special indications to warrant the use of the other.[1]

For the lateral method the only necessary instrument is the syringe which I now show. It is, in fact, Dr. Beehag's syringe with some modifications whereby the tube is shortened and is not screwed on the syringe but is simply adapted and fixed with a sort of ring. The patient must sit opposite a window so that his throat may be sufficiently in the light. The operator usually sits opposite the patient, but if the latter is in bed he can sit up and the operator must stand opposite him. If the injection is given at night a lamp must be used and, if possible, a frontal mirror. On a table near the operator there must be some boiling water to clean the tubes between the injections, some pieces of linen, a glass of water, and a basin, so that the patient may be able to rinse his throat after the injection and to spit out the fluid. The operator with his left hand draws the tip of the patient's tongue outside the mouth, while with his right hand he holds the syringe properly filled (i.e., containing no air) and introduces the tube gently, maintaining the curve in a horizontal position and passing over the lingual surface without touching it. The outside of the curve is then firmly applied to the base of the left faucial column, which is used as a support. The operator exerts a strong outward pressure on this column; by this means he keeps his hand steady when the liquid is projected forcibly, as it must be, otherwise his hand might tremble and the tube might irritate the patient's throat. In this position the tube is fixed like a gun on its carriage, its nozzle rests horizontally in the glosso-epiglottic groove, and the base of the tongue hides it. Its orifice is directed towards the lateral wall of the pharynx. Fig. 4 shows the syringe in this position. The patient remains passive and breathes without effort. The contents of the syringe are discharged with force; in fact, the liquid must be projected against the lateral wall of the pharynx with sufficient force to turn round this wall and thus reach the posterior wall, whence it falls into the larynx.

After the contents of the syringe are ejected the operator must keep the patient's tongue protruded for a few seconds so as to allow the liquid to run down, for the pharynx has the shape of a funnel only when the tongue is protruded and if the tongue resumes its natural position too soon the liquid, or a part of it, instead of running into the larynx is brought back into the mouth and expectorated. Immediately after the injection the patient feels a vague and rather agreeable sensation in his chest. He then spits out the small quantity of liquid that may remain in his pharynx and rinses his throat and mouth. You will now understand how simple and easy tracheal injection is.

FIG. 4.



G. Reignier del.

Tracheal injection; lateral method.

I will in the next place consider what medicines are to be injected. I have said that the early operators used menthol and creasote dissolved in olive oil, but these medicines are irritating and difficult for the patient to take. Instead of these I use non-irritating liquids and I now recommend eucalyptol and gomenol dissolved in olive oil—from 5 to 10 per cent. of the former and from 5 to 50 per cent. of the latter. Many other medicines might be used, as any substance which is not irritating may be injected into the trachea. In the first sitting, however, it is better to begin by injecting a very weak solution so as to ascertain the sensibility of the patient. The tolerance of the trachea is, as a rule, very great but in some exceptional cases the patient cannot take a solution containing more than 1 or 2 per cent. of the active component, otherwise he feels an irritation and may cough, but his coughing is always soothed by the injection of pure olive oil. The treatment by tracheal injection, or more simply, the tracheal treatment, consists of the injection of three consecutive deliveries from a syringe the capacity of which is three cubic centimetres, so that nine cubic centimetres of medicated liquid are injected every day. This treatment is continued for one month, after which it is discontinued but may be resumed as frequently as the condition of the patient requires it.

---

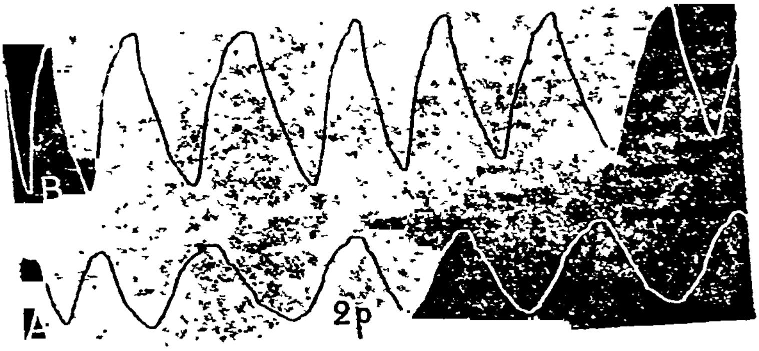
FIG. 5.

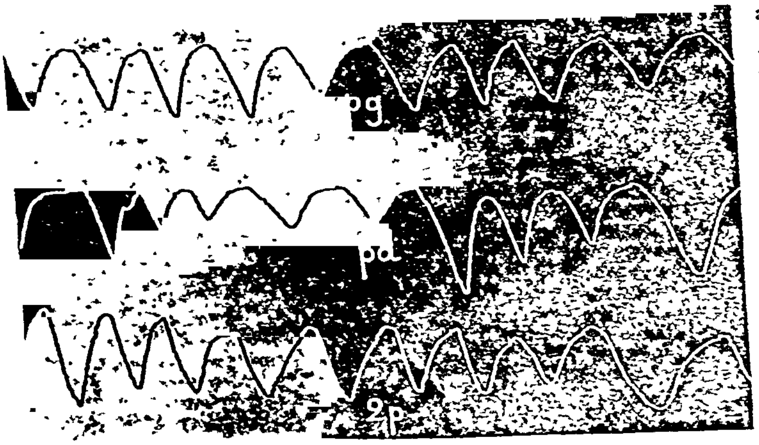


Pneumographic diagram.

Before showing you the method of giving an injection I will consider the clinical results of this treatment, results drawn from the observation of more than 200 patients within seven years. These results are of two classes, general and local.

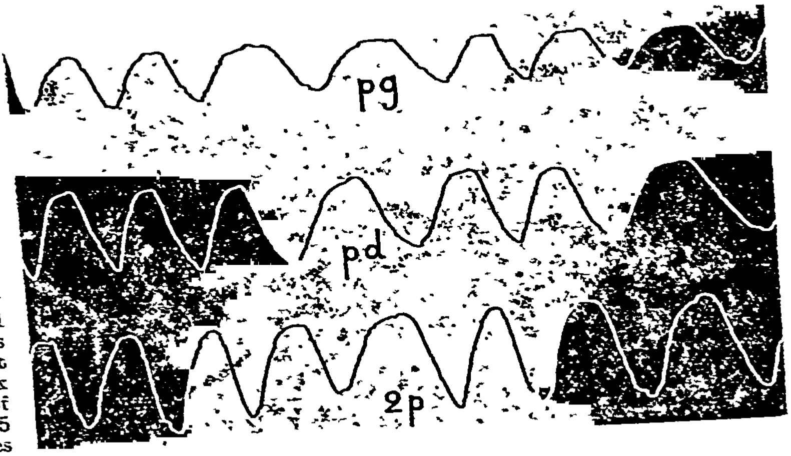
General results.—In the first place, gastric medication being avoided, the patient is not obliged to swallow drugs, which often cause dyspepsia by their action on the gastric mucous membrane. In the next place there is an immediate improvement in the respiration. This result may be considered as characteristic of tracheal treatment. As soon as the essential oil has penetrated into the bronchial tubes it evaporates and the vapour causes a reflex expansion of the lungs or of the parts of the lungs which are able to expand. Fig. 5 is a pneumographic diagram which gives in A a tracing of the respirations of a consumptive patient in the first stage of the disease, the tracing being taken before the first injection. The patient, still wearing the pneumographic belt, then received the injection and his respirations gave the tracing represented in B. It is obvious that the respirations shown in B are at least twice as deep as those shown in A. The patient naturally felt this difference before the pneumograph recorded it. This expansion is always greater in the hour or hours following the injections, but by degrees it becomes permanent, and in favourable cases within a few days the respiration is quite altered. Fig. 6 shows tracings of the respirations of a patient in the first stage of pulmonary tuberculosis with dulness and diminution of the respirations of the right apex. These records were made before the commencement of the tracheal treatment. The tracing *2p* represents the combined respirations of both lungs; *pd* represents the respirations of the right lung, and *pg* those of the left lung. Fig. 7 shows tracings of the respirations of the same patient after eight injections. It will be seen (1) that the respirations, especially those of the right lung—the diseased one—are now increased; (2) that the general expansion is greater; and (3) that the number of respirations per minute is less (17 instead of 22), which proves that every respiration is greater than before the treatment. This action on the respiration is of the utmost importance, for consumptives may be considered as taking in less air than normal individuals and the result of improving their respirations is to give them appetite, increase of weight, and, finally, more vitality.

FIG. 6.



Pneumographic diagram.

FIG. 7.



Pneumographic diagram.

Local results.—I may particularise the three following local results of the tracheal injections—namely, (1) daily "dressing" of the larynx; (2) diminution or cessation of the cough and expectoration; and (3) improvement of the stethoscopic signs. 1. The injection is a veritable cleansing of the larynx, where phlegm too often remains and becomes dry: this is the frequent origin of tuberculous laryngitis, and even in cases of laryngitis the injection is a good remedy. 2. In four-fifths of the observations the gravity of the cough diminishes or ceases, according to the case. At the same time, the expectoration becomes thinner and white and diminishes or even ceases altogether. As for the pyrexia it is rarely affected. In some cases, when pyrexia is caused by the filling of a cavity with phlegm, as the treatment has the effect of emptying this cavity by making the patient expectorate the temperature naturally falls. 3. In half of the cases I have been able to observe: (*a*) Expansion of parts of the lungs which did not expand before; in other words, the respiratory murmur becomes more audible in the apex where it had before been diminished. This result has been already noted by the pneumograph. (*b*) Another stethoscopic result which I have repeatedly observed is that the tracheal treatment checks the abnormal secretion from [illegible] aces, and this result has been [illegible] ution or disappearance of the [illegible], cavernous, or simply dry.

After this short exposition of the tracheal method, which, you perceive, may be used not only in tuberculosis but in any chronic broncho-pulmonary disease, I next proceed to give you some clinical demonstrations of the simplicity and efficacy of the process which I employ. I first show you a patient on whom tracheotomy was performed two years ago for syphilitic laryngitis. I remove the tube from his trachea and I give him a tracheal injection through his mouth by the simplified method. You can see the liquid, which is oil coloured red, running out of the opening in his trachea. Finally, I will give the injection to ordinary patients. You will see that this operation is rapid, simple, and not at all disagreeable to them.

ON THE HOURS OF SLEEP AT PUBLIC SCHOOLS,[1]

BASED ON AN INQUIRY INTO THE ARRANGEMENTS EXISTING IN FORTY OF THE GREAT PUBLIC SCHOOLS IN ENGLAND AND OTHERS IN THE UNITED STATES OF AMERICA.

BY T. D. ACLAND, M.A., M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN TO ST. THOMAS'S HOSPITAL AND CONSULTING PHYSICIAN TO THE HOSPITAL FOR DISEASES OF THE CHEST, BROMPTON.

IT may possibly be asked why one who is not a medical officer to a great public school should take up the question as to the hours of sleep which are desirable for boys at school. The explanation is a simple one. My interest was excited by a particular case and during the inquiries which ensued it seemed to me that it might be no bad thing for an outsider to introduce a discussion on this subject, especially if, like myself, he had no preconceived ideas and no traditions to influence him by casting an enticing and romantic haze over practices which belong to a bygone age but which are in many ways opposed to the more enlightened views of modern hygiene. There cannot be any question that sufficient sleep is a matter not only of importance but of vital necessity to the well-being of all young and growing children, especially at that period when the rapid unfolding of new bodily and intellectual functions makes it more than ever desirable that they should not be subjected to any influence which may retard or prevent the full development of their powers. A physiological question such as the one under consideration, which involves more than a third part of a boy's life, is surely one on which the Medical Officers of Schools' Association may be asked to express an opinion. Judging by some of the correspondence which has lately appeared in the daily press on the subject of our public schools there are still some persons who think that dirt, lack of cubic space, and insufficient food are Spartan conditions which tend to promote hardihood and intelligence, and that cleanliness, good food, ample ventilation, and common-sense regard for health encourage self-indulgence and coddling. Although much has been done to improve the condition of our great schools during the last 25 years it is within the knowledge of us all that there is still room for improvement, especially in matters relating to health. My object to-day is to discuss with you the question as to the amount of sleep which it is desirable to give to the younger boys during the first two or three years of their life at a public school, when they have not yet become acclimatised to their new conditions and when they are subjected to pressure of various kinds such as they have never before experienced, whilst at the same time they have reached a crisis in their lives which necessitates the most watchful care to enable them to attain to the maximum of intellectual and bodily efficiency.

Much is said about over-pressure in schools and all of us must know of cases in which actual breakdown has occurred. I know of many and my belief, which is shared by others who have ample opportunity for observation, is that a part, at any rate, of the harm is done by too little rest being given to the higher nerve centres owing to insufficient or broken sleep. Up to the time when this question first began to interest me I had assumed (as doubtless many have done before) that the hours of sleep in any great school were apportioned on some plan which had been carefully thought out between the medical advisers and the executive, and it came to me as something of a surprise to find that in a school in which the medical officer has for many years strenuously advocated the necessity for giving the boys up to 16 years of age ten hours' sleep a small boy of 13 years was placed in a dormitory in which the prefects' lights were not out and the dormitory was not quiet until 10.30, the boys being roused again at 6.15, giving, in fact, only seven and three-quarter hours of quiet.

It is generally held that an average of about eight hours' sleep is good for adults after they have attained their full development and during the best years of their active work. Some, of course, require less; some few require more. It is largely a matter of idiosyncrasy. There is much practical and some experimental evidence on this point. One distinguished member of our profession, a man of great physical strength, whose intellectual power was recognised by all who knew him, when under the full stress of work often required, and took, ten. Another tells me he cannot do with less than eight and a half and another nine. Eight hours' sleep seems to be a reasonable average for an adult when engaged in active work. It is admitted by all that the growing boy needs more sleep than the adult man. It cannot, therefore, be unreasonable to ask that boys who are just emerging out of childhood, when they are working and playing harder than ever before, should have fuller hours of sleep than those which not unreasonably would be granted to a hard-worked man. "Truth," as Ruskin says, "is not to be discerned by the uneducated senses." A clear perception of what is needed must depend upon previous knowledge and the exercise of trained observation. Those who have the care of growing boys ought not to be satisfied that long hours of work and strenuous play, combined with short hours of sleep, are desirable for them without careful inquiry, nor without taking counsel with those who have opportunity of looking a few years ahead and who are able to scan the horizon of the boy's future life after he shall have reached maturity.

I cannot doubt that the trained experience of the physician, who is able not only to watch the effect of school life upon the boy but also to observe its after-effects, is a safer guide in the ultimate decision of all questions relating to health than that of the layman who has not the technical knowledge and whose observation is mainly limited to the four or five years of the boy's public school life. The consequence of lack of repose to the body and central nervous system may entirely escape the notice even of a careful and experienced master. I have been told that it is not noticeable that the younger boys suffer more from illness than the older ones and that they do not show any ill-effects from lack of rest. To an untrained observer nothing may appear to be wrong, whilst all the time the boy may be working under a strain to his nervous system, which, before many years have passed, may work out its nemesis in some neurosis, such as neurasthenia, chorea, or even epilepsy. We unfortunately know only too well that the first positive evidence of nerve strain may indicate damage, the effect of which will last through life. "The mischief," an expert[2] writes to me, "is that the evil consequences ...... do not always show themselves at once, but are cumulative and come to the surface (often) after the boy has left school." I know of such cases, and there can be few here present who have not seen them; and which of us would like to apportion the blame with confidence between overwork, under-sleep, or idiosyncrasy? Surely, if there is a possibility of risk it is wiser to recognise it and not to subject the boy to any avoidable strain which is as unnecessary as it is contrary to well-known physiological laws.

How fallacious deductions made from a limited point of view or with preconceived ideas may prove to be is shown by the following statement of a lay correspondent who writes: "What you and those who agitate with you for longer hours of sleep are doing is simply to encourage the luxury and self-indulgence which are eating the heart out of our English boyhood and manhood and which show themselves nowhere more than in the matter of oversleeping." This is a serious statement, if it be true, and is deserving of full consideration. I shall refer to it again later, but as bearing upon the question I may mention that in four schools in which both the master and medical officers give their opinion in each case the master states that he does not think the smaller boys in that particular school need more sleep, whilst the medical officer is of opinion that they do. To ascertain the facts as completely as possible I have, through the kindness of many correspondents (to whom I here tender my sincere thanks), obtained the approximate hours of quiet in the dormitories in 40 of the great schools in England and in five of the largest and best schools in America[3] (Tables I. and II.) and I have obtained the opinions of a great number of observers in all parts of the country, especially of those who have written on the subject in standard works. I am thus enabled to lay before you a weighty mass of opinion, gathered from masters and medical officers of schools, physiologists, and physicians. From all quarters comes the same reply: growing boys need from nine to ten hours of sleep, the majority say *ten* should be given to the younger boys—e.g., from 13 to 16 years of age—if the body and central nervous system are to be maintained at their maximum efficiency (see Table IV. (A)). Here and there, but very rarely, a contrary opinion has been expressed but in no case has any defence of short—i.e., less than nine—hours of sleep been made by any medical officer of a school or physician. In the very few cases in which it has been made it has come from a layman who can hardly be fully acquainted with the medical side of the question. The fact is that the unanimity of the replies I have received has caused me some surprise. There has practically been no dissent from the opinion that the younger boys require, and frequently do not get, sufficient rest. If it were not that it seems to be unknown to some and is not acted on by others who have charge of the boys in our great public schools I should not venture to repeat the familiar message but the facts as they exist must be faced.

---

[1] A paper read before the Medical Officers of Schools' Association on May 11th, 1905.

[2] Sir James Crichton-Browne, M.D., F.R.S., Lord Chancellor's Visitor in Lunacy, writer of report on "Overpressure in Elementary Schools," printed by the House of Commons; Vice-President, Royal Institution, Great Britain.

There are three main points to be considered: (1) the allowance of sleep which is reasonable for growing boys during the first two or three years of their life at a public school; (2) the risk which is incurred by stinting young growing boys of that amount of sleep for which nature makes an imperative demand; and (3) some of the difficulties in the way of obtaining the needful amount of sleep in many public schools.

I will ask you first to consider the question from the point of view of the physiologist. Professor J. G. McKendrick[4] writes to me: "A young growing lad should have ten hours' sleep both during summer and winter. During the time they are at school and college there can be no doubt that the mental efficiency of boys is kept up to the normal standard by plenty of sleep. I have often noticed a jaded appearance when less sleep was obtained than, say, eight or nine hours, whilst the boy will be bright and alert if he has, say, ten hours. ...... I have known men who were no longer boys who still needed nine hours' sleep if they were to do effective work." Another distinguished physiologist, Professor C. S. Sherrington,[5] writes to me at length, condemning the practice of attempting to run the young boy's life with the same allowance of sleep which he considers necessary for the full-grown adult. He points out that the child's bodily life is run more expensively than the adult's, since bulk increases as the cube and surface as the square the child has, relatively, far more body surface than the adult and has in consequence to produce more body heat to maintain its temperature. This is proved by the fact that the average child gives out about 500 cubic centimetres of CO_2 per kilo of body weight as against 300 given out by the adult. The combustion in the child is more active than when growth has ceased; and further, there is the additional drain caused by growth and the characteristic restlessness of boyhood; from all of which points, which are incontrovertible, he deduces that solely on physiological grounds the body of the child demands a diurnal balance of repose much greater than that which is required in later life—in short, that boyhood wants longer sleep than does set manhood. "During sleep the chemical processes of the body are reduced in the case of CO_2 output to one-fifth, so that the organism during sleep may be said to have its fires banked instead of being run under forced draught. But sleep is not only a respite from chemical change, it is a mechanical rest as well, which is especially of importance during the years of growth. By insufficient rest the growth can be stunted and development retarded. The heart and respiratory mechanism require for their efficient working a diastole (or rest period) equal to their working hours. Most of a boy's growth in stature is done in bed and there mental and physiological recreation goes on most efficiently; without plenty of sleep the activity of the waking day is like a house built on sand—in constant danger of breaking down and giving way." He concludes by saying: "I should put the length of rest in bed demanded 'by small boys'—e.g., boys from 13 to 15 years—at ten hours and their normal hour for retiring

TABLE I.—*Showing the Approximate Hours of Undisturbed Rest in 40 English Public Schools.*

—	Younger boys.		Older boys.		Duration of winter hours.
	Summer.	Winter.	Summer.	Winter.	
1	10½	10½	8½	9½	Same all the year for juniors.
2	10	10¼	9½	9½	Two winter terms, 24 weeks.
3	9¾	10¼	8¾	9½	Not stated.
4	9¾	10	8¼	8½	About 8 weeks.
5	9¾	9¾	8¼	8¾	Same all the year.
6	9¼	9¾	8½	8¾	Not stated.
7	9¼	10 h. 10 m.	8½	9 h. 20 m.	About 14 weeks.
8	9¼	9½	9¼	9½	Not stated.
9	9¼	9¼	8½	8½	Same all the year.
10	9¼	9½	8¾	?	About 9 weeks.
11	9¼	9¼	9¼	9¼	Same all the year.
12	9	10	8	9	24 weeks.
13	9	10	8½	9½	About 8 weeks.
14	9	10	8½	9½	"
15	9	9½	9	9½	24 weeks.
16	9	9½	8½	9	About 15 weeks.
17	9	9	8½	8¼	Same all the year.
18	8¾	8¾	8	8	"
19	8 h. 40 m.	9½	8 h. 40 m	9½	24 weeks.
20	8 h. 40 m.	8 h. 55 m.	8 h. 40 m.	8 h. 55 m.	About 8 weeks.
21	8½	9½	8½	9½	24 weeks.
22	8½	9¼	8½	9¼	"
23	8½	9¼	8½	9¾	"
24	8½	9½	8	9	About 5 weeks.
25	8 h. 25 m.	9¼	8 h. 25 m.	9¼	About 10 weeks.
26	8½	9½	8½	9½	Not stated.
27	8½	9	8	8½	24 weeks.
28	8½	9	7½	8	About 3 weeks.
29	8½	9	8½	9	About 12 weeks.
30	8½	9	8½	9	About 6 weeks.
31	8½	8¾	8½	8¾	Not stated.
32	8½	8½	8	8	Same all the year.
33	8½	8½	8½	8½	"
34	8½	9¼	8½	9¼	A few weeks only.
35	8½	9	8¼	9	About 18 weeks.
36	8¼	9	—	—	24 weeks.
37	8¼	8¾	8¼	8¾	Not stated.
38	8¼	8¼	8¼	8¼	Same all the year.
39	8	9	8	9	A few weeks only.
40	7¾	8¼	7¾	8¼	For some weeks.

---

[3] A form of inquiry was sent to all the principal public schools in England and in a large number of instances, where the information was not sufficiently exact, subsequent inquiries were made. I am under a deep debt of obligation to my many correspondents, some of whom I should like to mention by name, were it not for obvious reasons undesirable.

[4] Professor McKendrick, M.D., F.R.S., Professor of Physiology in the University of Glasgow, formerly Fullerian Professor of Physiology, Royal Institution of Great Britain, and writer of the article on Sleep in the "Encyclopædia Britannica."

[5] Professor Sherrington, M.D., F.R.S., Holt Professor of Physiology, University of Liverpool, chairman of the British Association Committee on School Hygiene.

at 9"; and he adds, as is universally admitted, "the wants of all children are not the same—it is a question of idiosyncrasy."

Thus speaks the physiologist in no uncertain terms. In his opinion there are not two sides to this question. I hear it objected, however, that this is all very well but it is pure theory—the speaker has no practical experience of the education of boys and their actual needs. Far from this being the case, Professor Sherrington is not only a distinguished physiologist but he is also the chairman of a committee appointed by the British Association to report on the conditions of health essential to the carrying on of the work of instruction in schools and for some years he has given special attention to the subject.

TABLE II. (A).—*Showing the Hours of Sleep given in Five of the Principal American Schools.*

—	Younger boys.	Older boys.
1	10 and 9¾ according to age.	9½; sixth form 9.
2.	10 winter, 9½ summer.	9½ winter, 9 summer.
3	10 to 9½ under 16 years.	9 from 16 to 18 years.
4	10¼ under 15 years.	9 hrs. 20 min. over 15 years; sixth form 8 hrs. 55 min.
5	10½ to 9 according to age.	Sixth form 8½.

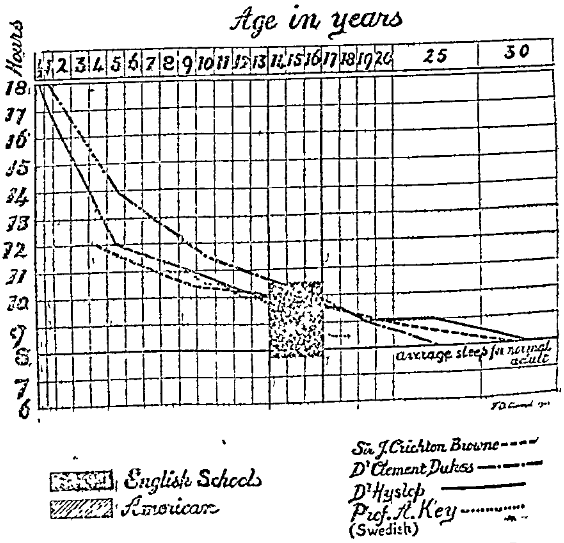
Note.—In none of the above schools is there chapel or school before breakfast at any time during the year.

TABLE II. (B).—*Showing the Hours of Sleep given in Certain Training Ships and Institutions.*

—	Hours of sleep.	Limit of age.
Training ship A	8¾ to 9	Up to 16
" " B	9	" 17
Royal Naval School	9¼	" 15½
Reformatories	8¾ to 9¼	" 16

If the words of the man of science cannot carry conviction let the house master in one of the most celebrated schools in England speak. He writes: "On the general principle of giving boys more sleep I am quite with you and will support any reasonable proposal when made for reform." And, further, the headmaster of one of the best schools in America says: "You will see that we give the boys a good deal more sleep than they have in public schools in England. I was myself at Cheltenham College for five years and I feel convinced that we were not allowed enough time for sleep. At this school boys up to 15 are allowed 10¼ hours; over 15, if not in the sixth, nine hours 20 minutes; sixth form, eight hours 55 minutes." So that in this school more sleep is given to the sixth form boys than in many English schools is allowed to children of 13 and 14. The headmaster of another school (this time an Englishman), who was for 14 years assistant master at one of the great schools, where the hours of quiet in the dormitories are given as eight and a quarter and eight and three-quarters in summer and winter respectively, writes to me: "As to sleep, the fact that I aim at nine [hours] for myself will show you my belief on the subject. In the winter we have no work before breakfast. The bigger boys get nine and a half hours' sleep in the winter, for silence is enacted at 10 P.M. . . . The little boys are in bed at 9, are called at 7.30, and are down at 8, so they get 10½."

To turn to the medical aspect of the case Dr. Clement Dukes, whose writings on school hygiene are widely consulted by all educational authorities, in the address which he gave before the Congress on School Hygiene in February last (1905), said: "If we follow nature, during the years of formation and development adequate sleep must not only be permitted but enforced. When puberty arrives and new functions are being established more sleep still is imperative, as is also the case in cold weather. The long hours of work demanded of the younger children, with the short time allowed for sleep could not be continued if the scheme were in force all the year round, as there would be no children left at the school. The vacations save a complete breakdown." He concludes by saying: "It is both unwise and unnatural to arrange suitable hours of work and sleep for the seniors in schools, to which juniors have to conform with serious injury to their present and their future. According to Dr. Clouston there is a decreasing degree of staying power manifest during the last 30 years (i.e., since the Education Act of 1870) on the part of the brain, to the extent of about 40 per cent. It is a question for us all to consider what share, if any, schools have in this terrible fact with the excessive hours of work in the early years of childhood, and totally inadequate amount of sleep during the same period of life."[6] Dr. T. B. Hyslop, senior physician to Bethlem Royal Hospital and King Edward's Schools (London and Witley), is not less emphatic. "My experience in Bethlem," he says, "tells me that the question of sleep is worthy of our most serious attention. ...... 90 per cent. of the cases admitted to Bethlem since the year 1820 have suffered from insomnia. That one of the essentials of life (as sleep is) should be so prone to be disordered is significant that there is a fault in our economy and this fault seems to arise from the fact that few, if any, of those who have charge of our boys and girls pay any attention to the cultivation of the *habit* of sleep.[7] The stress and strain of modern life necessitates increased brain activity, and in order that the mental energies may last it is obvious that brain rest should be obtained. Insomnia, brain fatigue, neurasthenia, are products of the last few decades and nearly all the cases I have to deal with have histories of overwork and inability to obtain a sufficient amount of rest. Oh! if only the people could be made to understand that the cultivation of the habit of sleep means an investment or insurance against the mental and nervous maladies of the present day. ...... Each decade sees us becoming more brainy, but the alertness of our youths and adolescents is shorter lived and premature degenerations are the almost inevitable outcome of a false economy in the use and abuse of brain power. On several occasions I have spoken about the tendency to later hours and their train of evils, but the people will awaken themselves to the truth only when it is too late. ...... The increase in mental and nervous instability demands a reversal of the engines of education, and I would regard sleep as the best preservation



This chart has been compiled from figures given by Sir J. Crichton-Browne ("Health and the Nervous System," Cassell's Book of Health, p. 296); Dr. Clement Dukes (Health at School, fourth edition, Rivingtons, 1905, p. 130); Professor A. Key* (Handbuch der Schulhygiene Burgerstein und Netolitzky, IIte. Aufl., Jena, 1902, p. 692); from an unpublished diagram by Dr. Hyslop, and from data obtained from the various public schools (cf. Tables I. and II.) In 23 out of the 40 English schools of which I have obtained particulars, the hours of sleep given to the younger boys fall short of the *minimum* for all or part of the year, and even the hours given to the older boys are in many instances insufficient.

* Professor Key allows one hour in the dormitory for rising and going to bed in *addition* to the hours given in his table.

---

[6] Sleep in Relation to Education, by Dr. Clement Dukes, physician to Rugby School, author of Health at School. Fourth edition. Rivingtons, 1905.

[7] During the discussion on this paper Dr. G. H. Savage, consulting physician to Guy's Hospital, late medical superintendent to Bethlem Royal Hospital, spoke strongly to the same effect.

against the stress and strain of life and all the incidental conditions which make so many succumb in adult life. I have been some considerable time in making out a chart of the relationship of sleep to age; the reason for the various estimates are based upon deeper considerations than those of temporary expediency (see Chart). ...... I have had charge of 480 children, 11 to 15 years of age, so I have had opportunities of studying the question."

I should like here to call attention to two papers by Dr. Hyslop on "Mental Hygiene in Childhood"[8] and "The National Basis of Education."[9] In these he points out the evils of defective brain rest and he draws attention to the symptoms of what he calls mental indigestion, such as nightmares, night terrors, somnambulism, epilepsy, and even convulsions, and he speaks strongly on the culpable ignorance of those who are responsible for the education of children, inasmuch as they attribute the formidable array of neuroses with which the expert has to deal merely to constitutional defect, whereas, in fact, it is to the system of education rather than to the child that the maladies are due. Ignorance on these points, he concludes, is all the more reprehensible, because it is within the power of those responsible to obtain enlightenment from those who, having had the necessary medical training, are well qualified to advise them.

One of your members, himself a distinguished medical officer of a great public school, writes: "The arrangements which still obtain in many schools under this head (the hours of sleep) are no doubt physiologically wrong and economically unsound. It is obviously unreasonable that the child who, if his parents are at all wise, is allowed his fair allowance of sleep within proper hours, during the holidays at home, should be docked of a substantial part of his physiological income just when the call upon it is greatest, that is at school."

Next let me quote Sir James Crichton-Browne whose work on Over-pressure in Schools is so well known. He writes: "You will be doing a public service by calling attention to the matter and by insisting on the importance of the *vis dormativa* in early years." He adds that he has not the shadow of a doubt that obvious and immediate harm results *from short hours of sleep and is certain that much and very* serious deferred harm may result from them. He continues: "Highly strung, sensitive boys suffer at once from loss of sleep ...... The more stolid and stable boys suffer covertly in slight retardation of brain growth and intelligence, not so obvious but real enough. Sleep is more intimately connected with brain growth than with brain function. In the years of highest cerebral activity in adult life least sleep is required, in the years of low functional activity, but rapid growth, most. ...... I have noted as one of the causes of the physical deterioration that is, I believe, going on, insufficiency and dislocation of sleep. This is a sleepless age and more and more ...... we are turning night into day. The sleep of the rising generation is being seriously interfered with, abbreviated, and broken, and the inevitable consequence must be a rich crop of 'neurotism' and a general lowering of the level of intelligence."

These are strong words coming from a trained observer who has devoted more than 30 years to the study of disorders of the nervous system and who has made a special study of the evil results of over-pressure in schools which has deservedly received wide recognition. 23 years ago he wrote: "From birth when the brain is growing rapidly and when life is almost a continuous sleep, onwards till manhood when brain growth is at an end and when only a third of existence is (or ought to be) given to sleep, the increment of growth progressively diminishes, and *pari passu* with this diminution in growth goes a reduction in the demand for sleep made by the system, so it might perhaps be said that eight hours in the 24 constitute the amount of reparative sleep needed by the full-grown brain and that all sleep beyond that amount prior to maturity is germinal sleep connected with processes of growth and development."[10]

If this is a reasonable statement of the case it follows that to give the adolescent brain a bare eight hours' sleep is to stint the growing boy not only in the time needed for the processes of development and growth but to impair the efficiency of those higher nerve centres on whose well-being the future of the boy's intellectual standard so largely depends. Nothing is more certain than that the improvement of the community turns upon the proper care and management of its children and no temporary success in obtaining scholarships at the universities and other distinctions, which are so often unreasonably accepted as the standard of efficiency of a school, can compensate in any way for the disregard of the plain teachings of physiology as to the relations of work and sleep which must in the long run be obeyed if the mass of ordinary boys are to be turned out fitted in the best way of which they are capable for taking their places as citizens of a great empire. Dr. Welldon, formerly headmaster of Harrow, draws attention in one of his speeches to a fact which had impressed itself upon him—namely, the number of clever brilliant boys he had known who in after life had absolutely disappeared. As Dr. Dukes remarks: "He did not recognise that these boys' immature brain tissue was exhausted before manhood."[11] In these days when athletics count for so much at school it is well to recognise that ample sleep is needed not only to render the brain and nervous system fit for active work but that it is not less necessary to maintain the muscles of an active boy in good sound condition.[12] Those who train men of picked physique for great races know this well and insist (as one of the most celebrated oarsmen of our generation informs me) on a good eight and a half to nine hours' sleep for those in training. These men, wise in their generation, do not see how much the crew can stand, nor run any avoidable risk of tiring them out before the final struggle has begun, a wisdom which it is to be feared is not always to be found in those who have the training of our youth for the great race of life.

TABLE III.—*Synopsis of Hours of Undisturbed Rest given to the Younger Boys in 40 English Public Schools.*

Class.	No. of Schools.	Ample hours.	Moderate hours.	Short hours.
A.	5	9¾ to 10 or more all the year.	—	—
B.	2	9½ to 10 the two winter terms.	9 during the summer term.	—
C.	7	9½ to 10 *for a few weeks only.*	9 to 9½ the chief part of the year.	—
D.	3	—	9 to 9¼ all the year.	—
E.	7	—	9 to 9½ the two winter terms.	8 to 8½ during the summer term.
F.	8	—	9 to 9½ *for a few weeks only.*	8 to 8½ the chief part of the year.
G.	8	—	—	8 to 8¾ or less all the year.

It is interesting to note that there appear to be only five out of the 40 English schools which come up to the highest standard, whilst in all five of the great American schools with which I have been put into communication, through the kindness of Professor W. Osler, the approved hours are given to the younger boys—namely, from nine and a half to ten; and further, four of the headmasters of these schools have expressed the opinion quite emphatically that these hours are desirable for the well-being of the boys. 50 medical experts, medical officers of schools, and others, have expressed a decided opinion that ample hours of sleep are needful for growing boys. Amongst these are included all in this country who (as far as I can ascertain) have written definitely in standard works on the question of sleep: Sir James Crichton-Browne, Dr. Clement Dukes, Professor Bradbury, Dr. Hyslop, Professor McKendrick, *and Professor* Sherrington, and besides these there are many whose names are honoured in English medicine and whose opinions cannot be disregarded on such a question as this. Such are Sir William H. Broadbent, Sir Thomas Barlow, Sir Lauder Brunton, Sir Dyce Duckworth, Professor Clifford Allbutt (Cambridge), Professor Osler (Oxford), Dr. Collier, Dr. Dickinson, Dr. Goodhart, Dr. Savage, Dr. Eustace Smith, besides 15 medical officers of the most celebrated public schools in England. It would be impossible to enumerate all, but the list includes many who have made a special study of diseases of children and disorders of the nervous system as well as those who have specially considered the subject in relation to modern education. 27 have given the number of hours which they consider best; the remainder do not definitely specify the number of hours but speak emphatically in more general terms.

---

[8] Clinical Journal, 1904, vol. xxv., No. 8, pp. 113-22.

[9] A paper read before the Beckenham Medical Society, Jan. 13th, 1905, and shortly to be published.

[10] "Education and the Nervous System." In the Book of Health. Cassell and Co. Pp. 293, 294.

[11] "Remedies for the Needless Injury to Children involved in the Present System of School Education." An address delivered before the Incorporated Association of Headmasters at their annual general meeting held in London. Rivingtons, 1899. Pp. 7, 8.

[12] I have received an interesting letter from Mr. C. B. Fry on this point. Although he was at a school where he got nine hours' sleep he writes that he felt that he never had his sleep out and required more than he got; so much did he crave for sleep that often for the first week or so of the holidays he would go to bed about 10 P.M. and sleep till one or two o'clock and sometimes even till five o'clock the next day. He adds that this was not laziness but was absolutely a natural paying of himself back: he felt that he had lived on his capital.

TABLE IV. (A).—*Showing the Hours of Sleep desirable for Growing Boys.*

27 medical officers of schools and other medical experts advise the following hours:—

9 advocate	10 hours.
8 ,,	9½ or 9½ to 10.
6 ,,	9 to 9½ or 9 to 10
4 ,,	9 as a "*minimum*"

Not a single medical expert has advocated less than nine hours.

TABLE IV. (B).—*Summary of Opinions received from Medical Officers of Schools.*

15 are in favour of longer hours. All from schools which give short hours of sleep during all or part of the year.
13 consider the hours of sleep sufficient in their schools.
  In 10 of these schools nine hours or more are given throughout the year.
  In two for part of the year.
  In one only are short hours given throughout the year.
6 replies indefinite.
6 replies not received.

It may, I think, be rightly claimed that there is conclusive evidence to show that both on physiological and medical grounds ample hours of sleep are necessary for the best development of growing boys and that up to 16 years of age from nine and a half to ten hours of undisturbed rest in bed in winter, and from nine to nine and a half in summer, would be in no way excessive. Do they in practice get this amount and if they do not do they feel the strain? The first question may without hesitation be answered in the negative, since although in a limited number of schools some of the small boys may be in their dormitories for the length of time named there is practically no possibility, from one cause or another, of their having anything like this amount of sleep. Hours in dormitory do not, of course, represent hours of sleep, though from some of the replies I have received it would appear that they are reckoned as such. Even the number of hours in bed often do not represent hours of sleep where the boys are in dormitories, unless order is really maintained, as it appears to be in some few schools with good discipline and on the training ships. But in a good many dormitories, besides the talking and "ragging" which goes on, there are other serious disturbances of sleep which efficiently break the rest of all but sound sleepers. Amongst these have to be reckoned not only the turning up of lights when the older boys come to bed (so that although the small boys may get to bed earlier they have the light in their eyes until the older boys are settled) but also the practice of not having the dormitory reasonably darkened, a point which Sir William Gull considered to be of great importance. Thus the hours are not only curtailed by the daylight waking the boys long before it is time for them to rise, but the quality of the sleep obtained is in the case of light sleepers seriously interfered with.

It cannot be questioned that the quality of sleep is influenced by darkness and that to insure the most complete rest to the nervous system it is necessary that sleep should not only be unbroken by noise but also by the exclusion of strong light from the room. It is also important that dormitories and cubicles should be properly warmed and ventilated. Sir James Crichton-Browne writes: "A certain degree of bodily comfort is essential to the good quality of sleep, and quality is almost as important as quantity." These may seem trivial details but they are worthy the attention of those who have the well-being of young boys at heart. There are few blessings given to mankind greater than a capacity for good sound sleep; it makes work easier and more effective and probably more than anything else enables the happy possessor of the faculty to meet the strains which he must encounter in the struggle for existence. It is surely worth while for those who have charge of the young not only to give ample hours of sleep but to see that as far as possible the arrangements are such as to insure that the sleep is not disturbed, as it often is, by preventable or unnecessary causes. Those who have given attention to the subject know the importance of this. "Quality," writes Dr. Hyslop, "is as essential as quantity for the building up the preservative power of sleep." Dr. Savage also lays special stress on this point and it was a favourite maxim of Sir James Paget.

In few schools would it appear that any attempt is made to encourage the *habit* of getting proper sleep; in fact, it seems to be assumed that the less sleep a boy can do with the better it will be for him and the hardier he will become. Such an idea is, I believe, entirely fallacious. It is not much more difficult to educate a boy in good habits than in bad ones, and of the two there can be no kind of doubt that the boy who has acquired the habit of sleeping well will in the long run have greater staying power than he who has not learnt the need for giving his nervous system sufficient rest. One of my correspondents writes: "Happy the man who in the days of his youth has contracted the habit of sound regular sleep. The headmasters should really, I think, offer prizes to the best sleepers."

From all sides I have learned that short hours of sleep *do* often press heavily on the younger boys and are of no possible advantage to them. None are more emphatic on this point than the masters of private schools who keep in touch with the boys after they leave, and especially those who have sons of their own at the public schools, from whom they hear the truth. They are not quite so innocent as one of my correspondents who told me that he did not believe the small boys wanted more sleep because they never complained to the headmaster! In two great schools I am assured that boys are not infrequently taken into the sanatorium, not because they are ill, but because they are tired out. One distinguished member of our profession whom I can remember as a boy at the top of one of our great public schools writes: "As to sleep, I fully agree with you that boys, especially young boys, do not get enough at school. A little boy can honestly sleep the clock round and is all the better for ten hours. I remember that my condition as a little boy at school was one of perpetual want of sleep. I used to go to sleep at all sorts of inconvenient moments through the day in consequence. Another thing is the disturbance of the sleep of little boys by the elder boys coming to bed later. ...... That ought not to be." As showing the importance of what has been written I should like to emphasise the fact that 15 medical officers attached to 12 of the great schools in which the hours of sleep possible for the younger boys are amongst the shortest (Table IV., B) have expressed the opinion that longer hours of sleep are desirable. I have been told by one of the few who have questioned the soundness of my contention that it is clear that the younger boys do not want more sleep because if they are sent to bed early they chatter instead of going to sleep. But that they *do* want more sleep is clear from the fact that they have to be often roused out of deep sleep next morning and dress half asleep in silence (as I have been assured they often do), too weary to show any of that exuberance of spirits which is natural to the healthy boy. If it is a fact that small boys chatter as a rule when they have a chance of going to sleep it would only show that in this, as in other matters, they need education. If in other branches of the school curriculum, as in this question of sleep, the decision as to what was good for them were left entirely to the boys the whole plan of education would, I fear, very speedily be dislocated. Is it not the duty of those responsible for the order in a house to see that after a reasonable time for going to bed has been allowed silence is really enforced?

It is difficult to ascertain the precise hours of sleep which can be obtained in any particular school, since local conditions vary, as, for instance, in one house silence in the dormitories may be really enforced at a given hour, whilst in others no account may be taken of the fact that prefects keep a light, or elder boys cause a disturbance by going to bed long after the normal hour given as that at which the younger boys are settled. It is also clear that the hours of sleep generally adopted at any particular school can be modified by the house masters to some extent. The compilation therefore of such a table as Table I. is one of peculiar difficulty and the hours given must be taken to represent the general rule of the school rather than as applicable to any particular house in that school. I have given in Table I. the hours of sleep allotted to the older boys as well as to the younger ones and it will be seen that they also are often too short.

The general results of my inquiry, after careful sifting of the evidence, reveal some curious facts. In the first place, the hours of quiet which appear to be given to boys from 13 to 15 or 16 seem to range from 7¾ to 10½ in summer and from 8¼ to 10½ in winter. Again, winter hours vary from a few weeks in some schools to 24 weeks—i.e., the two winter terms, in others. There is also a wide diversity in the hours at which the boys are called.

TABLE V. (A).—*Showing Hours at which the Boys are Called in 40 English Public Schools.*

No. of schools.	Hours at which boys are called.
1	6.0 summer term; 6.45 two winter terms.
3	6.15 most of the year; 6.45–7.0 for some weeks.
3	6.30 all the year.
9	6.30 most of the year; 6.45–7.30 for some weeks.
6	6.30 summer term; 7.0–7.30 two winter terms.
1	6.30; not stated whether any difference in winter.
1	6.45 all the year.
3	6.45 most of the year; 7.0–7.30 for some weeks.
1	6.45 summer term; 7.30 two winter terms.
2	7.0 all the year.
1	7.0 most of the year; 7.30 for some weeks.
2	7.0 summer term; 7.15–7.30 two winter terms.
3	7.0; not stated whether any difference in winter.
2	7.15 all the year.
1	7.15; not stated whether any difference in winter.
1	7.30 all the year.

TABLE V. (B).—*Showing Hours at which Boys are Called in Five of the Principal American Schools.*

No. of schools.	Hours at which boys are called.
1	6.50 all the year.
3	7.0 all the year.
1	7.0 in summer; 7.30 in winter.

Some of those who are willing to admit that the hours for sleep given in the schools with which they are connected are too short raise certain objections to increasing them. They point out that there is a difficulty in arranging different hours for boys of different ages. Such an objection cannot be regarded as a serious one, for, after all, what can be done, and is done satisfactorily, in some schools might also be done in others.

The statement to which I have already referred, "that longer hours of sleep would encourage the luxury and self-indulgence which are eating the heart out of our English boyhood and manhood," requires consideration. If it be true, every writer on the subject of sleep in this country, as far as I can trace them, is wrong, since I am unable to find any statement in writings on school hygiene which justifies the giving of as little as eight hours' quiet in the dormitories to the younger boys or which gives any countenance to the belief that nine, nine and a half, or even ten hours is either morally or physiologically bad. Commenting on the statement just quoted the headmaster of a large school writes: "It is strange, indeed, to find anyone so mistaken as to the causes of whatever may be wrong with the upbringing of our youth as to attribute it to over-sleep. One sympathises with him in his fight against a tendency to luxuriousness and general slackness" (as we all do) "but I apprehend that it is a poor weapon to defy nature. We must look elsewhere for the cause." Professor George Darwin of Cambridge writes to me on the subject as follows: "If it is a question of giving up some hours in school, or giving up sleep, I say the former is immeasurably preferable. I ask further whether lack of due sleep is not responsible for much of the prevalent slackness in school, of which there is so much reason to complain." If it can be shown that from nine to nine and a half hours of actual sleep are a physiological necessity for the average boy it can hardly be seriously maintained that it is encouraging sloth to give it. Might it not just as well be argued that to give wholesome and sufficient food is encouraging gluttony, a comforting doctrine to those who do not care to face a difficult problem, but hardly one which is likely to satisfy parents or the boys themselves.

It is an equally unsatisfactory argument that short hours of sleep are a process of selection and lead to the survival of the fittest. This presupposes that the fittest are those who happen to need the least sleep, an wholly fallacious argument, as we all know, since those who are the least affected by a scanty allowance of brain rest during their years of growth are often the dull heavy boys, whilst the keen, sensitive, intelligent boys are the ones to suffer. A master of one of the large public schools and one in which the hours of sleep are comparatively good, writes: "The hours of rest could profitably be somewhat lengthened. …… I am inclined to think that specially in the case of the clever boys this increase of rest would increase the intellectual efficiency." Again, I have been told that to allow boys to lie in bed after the hour of 6.30, which seems specially hallowed by tradition, is to encourage them in habits of idleness. This entirely depends on the hour at which the boys can get to sleep. It is no use burning the candle at both ends. To give a new version of an old proverb:—

> "Late to bed and early to rise,
> Is neither physiological nor wise."

I believe in boys getting up early after a sufficient number of hours of sleep but not before; to allow them in the summer, when they have more play as well as their full allowance of work, to get into the habit of going to bed late is not defensible. The medical officer of a great school which stands comparatively high in this matter of sleep in consequence of the boys having separate rooms calls attention to this and says in summer he thinks the younger boys often do not get sufficient sleep; whilst another says that in his opinion "for a young boy not to be in bed till 10 and up at 6.30 is an unduly strained life." There seems to be a strong feeling that the difficulties of getting the boys to bed early are well-nigh insuperable and that the real solution of the difficulty is the abolition of school, or of chapel and school, before breakfast, even if not in summer, certainly during the two winter terms. There is a considerable body of opinion in favour of this abolition of school or chapel before breakfast. Three eminent physicians who have had special opportunities for arriving at a sound conclusion think the question ought to be faced and from medical officers of seven of the most important schools I have received expressions of opinion that it would be better certainly during the cold weather, if not all the year round, to abandon this practice, which is of doubtful utility, and is open to many objections. The master whose letter I have just quoted says: "I think this addition [to sleep] would be best made in the morning, as if sent to bed too early the boys would not go to sleep but be inclined to play and talk and the net result in rest would probably be diminished rather than increased. Boys, however, sleep quite soundly till late in the morning."

The objection to giving boys a fuller allowance of sleep, which needs most consideration, is the moral one. The headmaster of one of the great public schools which has produced many successful scholars, whilst admitting that many of the younger boys would be the better for more sleep than they get, urges this objection; he says that longer hours would give opportunities for those evil habits which have to be guarded against and which are so rightly dreaded in any community of boys. His argument is that if the boys are tired out when they go to bed and have to be roused from sleep in the morning they will have less temptation to evil. Such an argument I believe to be not only a libel on the average healthy-minded boy but I cannot help thinking it to be unsound, for the reason that no one was ever made moral by being made feeble. I cannot doubt that the only way to combat this evil is to make the boys healthy, active, and vigorous and to deal with the danger straightforwardly from the manly point of view. I would not have touched on the question but that it has been definitely raised in the course of my inquiries and has to be faced. I consulted Sir Constantine Holman on this point.

He has, as many of you know, been treasurer and on the council of a large public school for nearly half a century and has had wide experience in dealing with this problem; he tells me (and allows me to use his name) that physiologically it is quite certain that the younger growing boys need more sleep than those who have arrived at maturity and that an average of eight hours is needed for fully grown men in active work, whilst boys at the critical period of their development need more. He says he considers it absurd to suppose that the mere giving of an ample allowance of sleep would in any way tend to promote immorality; that, as a matter of fact, the difficulties arise at the commencement of the night and not in the morning, when the increase of sleep must be given if at all. He does not believe that with all the opportunities for evil (if the boys are so minded) the question whether they have a sufficient or insufficient amount of sleep can have any bearing whatever on the subject. This is, I believe, the common-sense view of a difficult problem; the danger cannot be avoided by aiming at weakness and repression but only by healthy teaching and inculcating self-control.

There are two other points which I must briefly mention. One is that boys are classified not by age but by place in school, so that the clever little boys, who really require longer rest than others of their age owing to the increased activity of their brains, get the shorter hours allotted to the older boys. The other is that the line between juniors and seniors seems generally to be drawn between 15 and 16 years instead of a year later. Boys up to 16 years of age are still growing and developing rapidly and need all the rest given to younger boys.

I think that I may rightly claim to have shown that in many of our schools this question of sleep has been too little considered and that the hours of sleep given to the younger boys, and I might almost say often to all the boys, are too short, whilst in others, although the needs of the younger boys have been recognised to some extent, the attempts to give them longer rest than the older ones, by sending them to bed earlier in the same dormitories, have failed for various reasons. I have tried to face the difficulties and answer the objections to giving longer hours of sleep and to show that physiology, medicine, and common-sense declare in no uncertain voice that to maintain the maximum intellectual and bodily efficiency of growing boys it is absolutely necessary not to stint their bodies and their nervous systems of rest. It seems to me that the logical conclusion is that the younger boys should be placed in separate dormitories, under effective supervision, or if, as some believe, it is better to have boys of different ages in the same dormitories that quiet should be insured for all, say at 10 P.M., and that during the summer months boys should be called at 7 and during the two winter months at 7.30. By this means from nine to nine and a half hours of quiet could with reasonable certainty be obtained. It may be urged that I am treading on dangerous ground; some may think that an attempt is being made to upset time-honoured traditions. To this I would reply that traditions based upon circumstances of life which have passed away are not necessarily the best guides for dealing with the conditions of to-day and that to respect traditions solely because they have been approved in the past make not for national efficiency but for national decay. The hurry and stress of life in the present day are infinitely greater than they have ever been before and the alarming increase in disorders of the nervous system is attracting the anxious consideration of those who have the best opportunities of estimating its extent. With these facts before us we ought to spare no pains to impress our convictions as to the necessity for carefully regulated hours of rest upon those who are responsible for the health and education of our boys, on whose intellectual efficiency and bodily vigour the future of this country so largely depends. In conclusion, I venture to hope that this Association may take the matter up and may be able to convince those who have the direction of our great schools that the subject of giving the younger boys ample sleep is one which is deserving of their most serious consideration.

THE INFLUENCE OF FRUIT ON THE PRECIPITATION OF THE URIC ACID OF THE URINE.

BY WILLIAM J. SMITH JEROME, M.A. OXON., M.B. LOND.,
LECTURER IN PHARMACOLOGY IN THE UNIVERSITY OF OXFORD.

FEW things perplex a patient more than the contradictory advice as to diet which is liable to be offered to him when consulting more than one medical man for the same ailment. The difference in question is doubtless due to our want of precise knowledge as to the effect of various foods, while this again is traceable, in no small degree, to the sacrifice of time and convenience demanded of those who undertake, or submit to, the experiments necessary for obtaining the desired knowledge. The subject, however, is important, and I hope through some experiments I have been making on myself to throw a little light on one or two of its many obscure points, one object of the work described below being to ascertain if there is a scientific basis for the practice, followed to some extent at any rate, of allowing certain fruits and denying others to those who suffer from uric acid calculus and gravel.

To ascertain the influence of an article of diet in increasing or lessening the tendency of the uric acid to spontaneous precipitation, it is of course necessary to have a means of measuring the precipitability of the acid in a given specimen of urine. If all specimens deposited uric acid on keeping the information could be obtained from a knowledge of the percentage amount of uric acid and the quantity precipitated in a given time under uniform conditions; but many, even acid, urines may be kept for very lengthened periods by means of antiseptics without any separation of their uric acid in a solid form. It is possible, none the less, by a very simple application of the known laws controlling solution and precipitation to obtain an available and satisfactory test.

A solid like uric acid will not be deposited from its solution until its solvent is supersaturated; while supersaturation, on the other hand, may be carried to a considerable extent without the occurrence of precipitation. If, however, ever so small a quantity of free uric acid is present in the solid state in such supersaturated solution, uric acid deposition will begin and continue till supersaturation has given place to saturation, equilibrium being established. The rate of deposition will vary with circumstances and is largely dependent on the surface area presented by the solid, while it is quickened by shaking, stirring, &c. These remarks apply to solutions of free uric acid and His[1] and Klemperer[2] have shown that a part, even as much as 96 per cent., of the uric acid of the urine may be in this condition. Part, however, is combined with base, and this portion will not conform to the rule stated until it has been set free by the addition of some strong acid which in the old phraseology was said to take the base by virtue of its stronger affinity for this, while it is now known that the result is determined by the feebler tendency of the weaker acid (uric) to undergo ionisation. We can, therefore, by adding a strong acid, free any uric acid which is combined with base and, provided that a mere grain of uric acid is present in the solid form, insure the deposition of all that is in solution over and above the point of saturation. But the strong acid serves another purpose—viz., that of lowering the saturation point in accordance with the law that the solubility of an electrolyte is lessened by the addition of another electrolyte which yields an ion in common with it. Besides the free uric acid and that which is combined with base there is a small quantity in the form of organic combination, but as this, for the knowledge of which we are indebted to His,[3] is not thrown down by acids, it does not need consideration in the present connexion.

The above principles are illustrated by the three following experiments, showing that while the rate of uric acid deposition is determined, *ceteris paribus*, by the amount of strong acid added, the quantity thrown down is independent of this, provided always that the acid is in sufficient quantity to liberate the whole of the uric acid which is combined with base and to start the precipitation and that time enough is allowed for the completion of this process. The period necessary is sometimes very long and is shortened by anything which so modifies the precipitation as to increase the surface area presented by a given quantity of uric acid.

---

[1] Therapie der Gegenwart, October, 1901.

[2] Verhandlungen des 20ten Congresses fur Innere Medicin, Wiesbaden, 1902.

Experiment A.

1. 50 cubic centimetres filtered afternoon urine, containing 0·0226 gramme uric acid, 1 drop dilute H_2SO_4 (= 6 1 cubic centimetres decinormal). Filtered through small filter after 48 hours. The uric acid, after washing with dilute HCl and then with alcohol was Kjeldahled and its (N) estimated. Amount of uric acid 0·0037 gramme.

2. 50 cubic centimetres of the same urine, 2 drops of the same acid (= 12·2 cubic centimetres decinormal). Uric acid deposit after 48 hours 0·0103 gramme.

3. 50 cubic centimetres of the same urine, 4 drops acid. Uric acid *deposit after 48 hours 0·0134 gramme.*

5 drops of $CHCl_3$ were added to each specimen in this and other experiments and the addition was repeated when considered necessary.

Experiment B.

Dec. 31st, 9 50 A.M.: 50 cubic centimetres urine, 1 drop dilute H_2SO_4 *(= 4·39 cubic centimetres decinormal).*
Feb. 15th, 5.10 P.M.: No deposit of uric acid.

Dec. 31st, 9.50 A.M.: 50 cubic centimetres urine, plus 2 drops acid.
Jan. 2nd, 10 P.M.: No deposit.
Jan. 3rd, 10 A.M.: 3 uric acid crystals.
Jan. 4th, 4.30 P.M.: A few more crystals.
Jan. 11th, 10.20 A.M.: General *deposit of uric acid.*
Feb. 15th, 5.10 P.M.: Filtered. Uric acid 0·0136 gramme.

Dec. 31st, 9.50 A.M.: 50 cubic centimetres urine, plus 3 drops acid. 8 P.M.: no deposit; 10.10 P.M.: *a few crystals of uric* acid.
Jan. 1st, 9.45 A.M.: Deposit increased.
Feb. 15th, 5.35 P.M.: *Filtered. Uric* acid 0·0147 gramme.

Dec. 31st, 9.50 A.M.: 50 cubic centimetres *urine*, plus 15 drops acid; 11.15 A.M.: uric acid precipitation begun.
Feb. 15th, 6.10 P.M.: *Filtered. Uric* acid 0·0130 *gramme.*

The total *quantity* of uric acid in 50 cubic centimetres *of the urine* used in this experiment was 0·0201 gramme.

Experiment C.

Nov. 21st: 100 cubic centimetres urine, plus 1 drop dilute H_2SO_4. 5.35 P.M.: *50 cubic centimetres* of this mixture, 20 cubic centimetres sodium urate solution, made by shaking excess *of salt with* water at *intervals* during 24 hours, filtering, warming the filtrate, and refiltering after the filtrate had cooled.
Nov. 28th: No uric acid deposit. Attacked by bacteria.

Nov. 21st, 5.35 P.M.: 50 cubic centimetres urine, plus 1 drop acid, plus 20 cubic centimetres sodium urate solution. 9 P.M.: No deposit.
Nov. 24th, 10 A.M.: A very slight precipitate of uric acid.
Nov. 26th: Turbid from bacteria.

Nov. 21st, 5.35 P.M.: 50 cubic *centimetres* urine, plus two drops acid, plus 20 cubic centimetres sodium urate solution. 9 P.M.: *Abundant* uric acid deposit.
Dec. 14th, 6.30 P.M.: Filtered. Uric acid = 0·0277 *gramme.*

Nov. 21st, 5.35 P.M.: 50 cubic centimetres urine, plus 3 *drops acid,* plus 20 cubic *centimetres sodium* urate solution. 9 P.M.: Abundant uric acid precipitate.
Dec. 14th, *8.30* P.M.: *Filtered.* Uric acid = 0·0225 gramme.

Nov. 21st, 5.35 P.M.: 50 *cubic* centimetres *urine*, plus 6 drops acid plus 20 cubic centimetres sodium urate solution. 9 A.M.: Abundant *deposit.*
Dec. 14th, 8 P.M.: Filtered. Uric acid = 0·0268 gramme.

Nov. 21st, 5.35 P.M.: 50 cubic centimetres urine, plus 20 *drops acid,* plus 20 cubic centimetres sodium urate solution.
Dec. 15th, 6.30 P.M.: Filtered. Uric acid = 0·0283 gramme.

Of the acid used in this experiment 1 drop = 4·39 cubic centimetres decinormal.

In Experiment A, in which the time allowed for precipitation was 48 hours, the quantity of uric acid thrown down by the addition of four drops of the acid used was nearly four times as great as that precipitated by one drop of the same acid from the same urine.

In Experiment B one drop of the acid employed was not enough to cause precipitation, but two, three, and 15 drops gave, after 46 *days*, practically the same amount of deposit —viz., 0·0136 gramme, 0·0147 gramme, and 0·0130 gramme.

In Experiment C no deposit was produced by half *a drop* at the end of *seven days.* 1 drop caused a precipitate on the third day but the specimen had *to* be thrown away because of the appearance of bacteria in spite of *the* $CHCl_3$ added to it. 2, 3, 6, and 20 drops precipitated each an amount which after 23 days was practically equal—viz., 0·0277 gramme, 0·0285 gramme, 0·0268 gramme, and 0·0283 gramme.

The result would of course appear more striking if larger quantities of urine were used, as the ratio of the inevitable error of observation to the total amount of uric acid precipitated would be thereby reduced, but when the results with small quantities can be readily and clearly interpreted these are to be preferred because of the time saved.

The influence of certain kinds of fruit in favouring or hindering the precipitation of the uric acid was tested on myself by ascertaining the *minimal* amount of added dilute sulphuric acid which sufficed to start precipitation within a given arbitrary time—viz., 48 hours. The urine of the 24 hours was collected at 10 A.M., measured, and diluted with distilled water, in Series 1 to 1500 cubic centimetres and in Series 2 to 2000 cubic centimetres. After careful filtration 50 cubic centimetres were put into each of several similar beakers and 1 drop of dilute H_2SO_4 of a known strength *from a burette and 5 drops of* chloroform added to one, which was at *once shaken to secure immediate mixing* of the acid, 2 drops of acid and 5 of chloroform were added to a second beaker, 3 to a third, and so on. The beakers, covered each by a watch glass, were placed together and examined *from time to time* with a lens. It is, of course, necessary that in any given experiment all the specimens shall be subjected, as far as possible, to the same conditions as to shaking, filtering, smoothness of *surface* of beakers, &c. The total nitrogen was estimated by Kjeldahl's and the uric acid by a slight *modification* of the Ludwig-Salkowski method, and the phosphoric acid by means of uranium acetate. My diet during the first series consisted of *café au lait*, dry toast and butter for breakfast; of *soup*, fish, *poultry or* meat, the latter generally veal, potatoes, and a green vegetable, with *two glasses* of light white Italian wine and a cup of black coffee, for lunch; while in the evening I took *only* a basin of bread-and-milk, followed by either tapioca or bread-and-butter pudding and one tablespoonful of brandy with soda-water. During the second series soup was omitted, red wine in the same quantity was taken instead of white, and in the evening the tablespoonful of brandy was left out. I should have preferred to have adhered always to the same meat and vegetable and to have weighed *the* quantities, but this is difficult in experiments extending over months, and the results prove sufficiently clear under the method adopted.

Series 1.

In Series 1 the fruit and non-fruit periods, each occupying *four days, followed one* another continuously, but in the second series a period lasted five days, the urine on the first day of each period not being examined. The fruits first used were pears, fresh figs, and grapes, and the weights given are *always those of the* pulp taken, apart from rind and seeds, when these were separable. The acid employed in Series 1 was of such strength that 1 drop = 1·9 cubic centimetres decinormal and the quantity of this needed to start precipitation of *uric acid during* the four days of the pear period was 2, 2, 3, and 3 drops respectively; total 10 drops = 19 cubic centimetres decinormal. During the following non-fruit period the amount was 2, 1, 1, and 2 drops; total 6 drops = 11·4 cubic centimetres decinormal. In the *fig* period 2, 1, 3, and 2 drops were needed; total 8 drops = 15·2 cubic centimetres decinormal. In the succeeding non-fruit period 1, 1, 1, and 2 drops; total 5 drops = 9·5 cubic centimetres decinormal. In the grape period 2, 3, 3, and 3 drops; total 11 drops = 20·9 cubic centimetres decinormal.

Non-fruit periods.	Fruit periods.
11·4 c.c. decinormal.	19·0 c.c decinormal.
9·5 ,, ,,	15·2 ,, ,,
	20·9 ,, ,,

There *is* no doubt, therefore, that in each *case* the fruit lessened the tendency to precipitation of the uric acid. In this series the amount of uric acid *was not determined* daily, but an estimation of it was made at the end of each period *in a mixture* of equal parts of the four days' urine. For the two non-fruit periods (Oct. 8th to 11th and 16th to 19th) the *daily mean* was 0·3240 gramme and 0·3360 gramme, while for the fruit periods it was 0·327 gramme (pears), 0·3940 gramme (figs), and 0·4330 gramme (grapes). The total nitrogen, acidity, &c., are given in Table IV.

Series 2.

The acid used for precipitating in this series was rather less strong than that employed previously—viz., 1 drop = 1·2 cubic centimetres decinormal, the amounts needed being:—

Date period ...	1, 2, 3, 3 drops;	total 9 drops	= 10·8 c.c. decinormal.
Non-fruit period	½, ½, ½, 3 ,,	,, 4½ ,,	= 5·2 ,, ,,
Orange ,,	4, 4, 4, 4 ,,	,, 16 ,,	= 19·2 ,, ,,
Non-fruit ,,	1, 1, 2, 2 ,,	,, 6 ,,	= 7·2 ,, ,,

He has, as many of you know, been treasurer and on the council of a large public school for nearly half a century and has had wide experience in dealing with this problem; he tells me (and allows me to use his name) that physiologically it is quite certain that the younger growing boys need more sleep than those who have arrived at maturity and that an average of eight hours is needed for fully grown men in active work, whilst boys at the critical period of their development need more. He says he considers it absurd to suppose that the mere giving of an ample allowance of sleep would in any way tend to promote immorality; that, as a matter of fact, the difficulties arise at the commencement of the night and not in the morning, when the increase of sleep must be given if at all. He does not believe that with all the opportunities for evil (if the boys are so minded) the question whether they have a sufficient or insufficient amount of sleep can have any bearing whatever on the subject. This is, I believe, the common-sense view of a difficult problem; the danger cannot be avoided by aiming at weakness and repression but only by healthy teaching and inculcating self-control.

There are two other points which I must briefly mention. One is that boys are classified not by age but by place in school, so that the clever little boys, who really require longer rest than others of their age owing to the increased activity of their brains, get the shorter hours allotted to the older boys. The other is that the line between juniors and seniors seems generally to be drawn between 15 and 16 years instead of a year later. Boys up to 16 years of age are still growing and developing rapidly and need all the rest given to younger boys.

I think that I may rightly claim to have shown that in many of our schools this question of sleep has been too little considered and that the hours of sleep given to the younger boys, and I might almost say often to all the boys, are too short, whilst in others, although the needs of the younger boys have been recognised to some extent, the attempts to give them longer rest than the older ones, by sending them to bed earlier in the same dormitories, have failed for various reasons. I have tried to face the difficulties and answer the objections to giving longer hours of sleep and to show that physiology, medicine, and common-sense declare in no uncertain voice that to maintain the maximum intellectual and bodily efficiency of growing boys it is absolutely necessary not to stint their bodies and their nervous systems of rest. It seems to me that the logical conclusion is that the younger boys should be placed in separate dormitories, under effective supervision, or if, as some believe, it is better to have boys of different ages in the same dormitories that quiet should be insured for all, say at 10 P.M., and that during the summer months boys should be called at 7 and during the two winter months at 7.30. By this means from nine to nine and a half hours of quiet could with reasonable certainty be obtained. It may be urged that I am treading on dangerous ground; some may think that an attempt is being made to upset time-honoured traditions. To this I would reply that traditions based upon circumstances of life which have passed away are not necessarily the best guides for dealing with the conditions of to-day and that to respect traditions solely because they have been approved in the past make not for national efficiency but for national decay. The hurry and stress of life in the present day are infinitely greater than they have ever been before and the alarming increase in disorders of the nervous system is attracting the anxious consideration of those who have the best opportunities of estimating its extent. With these facts before us we ought to spare no pains to impress our convictions as to the necessity for carefully regulated hours of rest upon those who are responsible for the health and education of our boys, on whose intellectual efficiency and bodily vigour the future of this country so largely depends. In conclusion, I venture to hope that this Association may take the matter up and may be able to convince those who have the direction of our great schools that the subject of giving the younger boys ample sleep is one which is deserving of their most serious consideration.

Bryanston-square, W.

RUSSIAN MEDICAL MEN NOT PERMITTED TO HOLD A CONFERENCE.—The village and factory medical men of the Moscow province proposed to hold a conference in the local government house to discuss matters interesting to the profession, but, according to the *Novoe Vremya*, the legal authorities refused them the permission to do so.

THE INFLUENCE OF FRUIT ON THE PRECIPITATION OF THE URIC ACID OF THE URINE.

BY WILLIAM J. SMITH JEROME, M.A. OXON., M.B. LOND.,
LECTURER IN PHARMACOLOGY IN THE UNIVERSITY OF OXFORD.

FEW things perplex a patient more than the contradictory advice as to diet which is liable to be offered to him when consulting more than one medical man for the same ailment. The difference in question is doubtless due to our want of precise knowledge as to the effect of various foods, while this again is traceable, in no small degree, to the sacrifice of time and convenience demanded of those who undertake, or submit to, the experiments necessary for obtaining the desired knowledge. The subject, however, is important, and I hope through some experiments I have been making on myself to throw a little light on one or two of its many obscure points, one object of the work described below being to ascertain if there is a scientific basis for the practice, followed to some extent at any rate, of allowing certain fruits and denying others to those who suffer from uric acid calculus and gravel.

To ascertain the influence of an article of diet in increasing or lessening the tendency of the uric acid to spontaneous precipitation, it is of course necessary to have a means of measuring the precipitability of the acid in a given specimen of urine. If all specimens deposited uric acid on keeping the information could be obtained from a knowledge of the percentage amount of uric acid and the quantity precipitated in a given time under uniform conditions; but many, even acid, urines may be kept for very lengthened periods by means of antiseptics without any separation of their uric acid in a solid form. It is possible, none the less, by a very simple application of the known laws controlling solution and precipitation to obtain an available and satisfactory test.

A solid like uric acid will not be deposited from its solution until its solvent is supersaturated; while supersaturation, on the other hand, may be carried to a considerable extent without the occurrence of precipitation. If, however, ever so small a quantity of free uric acid is present in the solid state in such supersaturated solution, uric acid deposition will begin and continue till supersaturation has given place to saturation, equilibrium being established. The rate of deposition will vary with circumstances and is largely dependent on the surface area presented by the solid, while it is quickened by shaking, stirring, &c. These remarks apply to solutions of free uric acid and His[1] and Klemperer[2] have shown that a part, even as much as 96 per cent., of the uric acid of the urine may be in this condition. Part, however, is combined with base, and this portion will not conform to the rule stated until it has been set free by the addition of some strong acid which in the old phraseology was said to take the base by virtue of its stronger affinity for this, while it is now known that the result is determined by the feebler tendency of the weaker acid (uric) to undergo ionisation. We can, therefore, by adding a strong acid, free any uric acid which is combined with base and, provided that a mere grain of uric acid is present in the solid form, insure the deposition of all that is in solution over and above the point of saturation. But the strong acid serves another purpose—viz., that of lowering the saturation point in accordance with the law that the solubility of an electrolyte is lessened by the addition of another electrolyte which yields an ion in common with it. Besides the free uric acid and that which is combined with base there is a small quantity in the form of organic combination, but as this, for the knowledge of which we are indebted to His,[3] is not thrown down by acids, it does not need consideration in the present connexion.

The above principles are illustrated by the three following experiments, showing that while the rate of uric acid deposition is determined, *ceteris paribus*, by the amount of strong acid added, the quantity thrown down is independent five days, the dose being 170 grammes for four days, 150 grammes for 19 days, and again 170 grammes for four more days. The diet in other respects remained as before. The results during the last four days agree with those of the four days of the former experiment (Table II.).

[3] Loc. cit.

It must be admitted therefore that marmalade does not increase the precipitability of the uric acid of the urine. No other sugar than that in the marmalade was taken during any of these experiments, saccharin being substituted.

In seeking an explanation of the *modus operandi* of the above fruits in diminishing the tendency to precipitation of the uric acid attention is naturally directed to the lessened acidity of the urine. But as the factors influencing uric acid precipitation from this liquid are numerous it seemed desirable to inquire if other changes, as well as that in the reaction of the urine, were operative in the experiments just described. I did not succeed in finding any. It is true that alcohol always caused a greater precipitate in the urine of the fruit periods than in that of the others when this point was tested and that the precipitate of the former periods had a greater solvent power for uric acid than that of the latter. This, however, can be explained by the influence of the altered reaction on the form assumed by the phosphates. The precipitate during all periods contained a diastatic ferment but the activity of this did not seem to be increased by the taking of fruit. As activity and quantity of ferment do not necessarily run parallel it is possible that the latter may have been augmented. The urine, in respect of

* It is to be noted that on three days of this period the urine exceeded 1500 cubic centimetres. This would be compensated in greater or less degree by the excretion of a larger quantity of uric acid in this than in any other period except the last.

The quantity of uric acid in 50 cubic centimetres of urine was :—

	Gramme.	Gramme.	Gramme.	Gramme.
Date period	0 0109	0 0100	0 0107	0 0100
Non-fruit period ...	0 0107	0 0107	0 0121	0 0116
Orange „ ...	0 0103	0 0107	0 0115	0 0116
Non-fruit „ ...	0 0100	0 0105	0 0091	0 0083

The daily average of uric acid was thus: 0·0104 gramme, 0 0112 gramme, 0 0110 gramme, and 0 0094 gramme for the four periods respectively and if the amount in the first non-fruit period is a little greater than that in the preceding and following periods and might be expected, therefore, to need somewhat less acid for precipitation, the quantity in the second non-fruit period is less than in any other period, though the total quantity of acid required to cause precipitation was only 7·2 cubic centimetres decinormal, against 10·8 cubic centimetres and 19·2 cubic centimetres in the two fruit periods. We have, therefore, clear proof that dates and oranges act like pears, fresh figs, and grapes in hindering the precipitation of the uric acid of the urine when taken in the quantities used in these experiments.

I tried next the effect of marmalade made with equal weights of sugar and oranges. The quantity taken daily was 172 grammes, 179 grammes, 170 grammes, and 185 grammes, the diet being in other respects unchanged. The acid used for precipitating was of the same strength as the last. The amounts of uric acid in 50 cubic centimetres of urine of the several days were 0·0084 gramme, 0·0085 gramme, 0·0086 gramme, and 0·0082 gramme, with a daily average of 0·0084 gramme. This is distinctly below that of any other period and a larger quantity of acid would therefore, other things being equal, be required to start the precipitation. The actual amounts needed were two, two, three, and three drops. Total, 12 cubic centimetres decinormal, against 19·2 cubic centimetres decinormal when oranges were taken. But the total amount of orange pulp consumed in the orange period was 1254 grammes, against 706 grammes marmalade and only half of this consisted of orange—viz., pulp *plus* rind. When, however, the natural acidity and the percentage of uric acid agreed in the marmalade and in the non-fruit periods a similar correspondence existed between the quantities of acid needed for precipitating (Table I.).

The difference between 2·4 cubic centimetres and 3·6 cubic centimetres is, indeed, 50 per cent. of the former, but it must be remembered that this difference corresponds to one drop only of the acid and if the experiment had been made more delicate by using a more diluted acid for precipitating the numbers would have approximated even more closely to each other. It would appear, then, either that the quantity of orange pulp contained in the marmalade taken was not sufficient to exercise a distinct influence in lessening the precipitability of the uric acid or that such influence was counteracted by that of the sugar mixed with it. On the other hand, there is no sign that the marmalade favoured the precipitation of the uric acid. Lest sugar should be capable of acting injuriously when taken for a longer period I continued the marmalade for 27 days, with an interruption of

The precipitation of uric acid evidently runs the same course in specimens containing equal amounts of this substance in both the fruit and non-fruit periods, provided that the degree of acidity is the same. If further confirmation of this were needed it is afforded by a comparison of the amount of acid required to cause precipitation with the normal acidity of the urine in the two periods in those cases in which the amounts of uric acid are exactly or nearly alike (Table III.). In only one case, the last, do the numbers differ from each other by more than corresponds to one drop of the acid used for precipitating (= 1·2 cubic centimetres decinormal); and this correspondence is as close as can be expected to occur. It would be closer in proportion to the degree of dilution of the acid used for precipitating. In the exceptional case in which the numbers are 11·6 and 10·2 I was in doubt whether to consider the precipitation as caused by one drop or by two drops of acid, for with one drop precipitation had really begun, but there were only five small crystals visible with the pocket lens, while on the following day the precipitation was general—one drop was less than was required and two drops were more. Had I taken one instead of two as the efficient number the figures would have been 10·4 and 10·2. It may be maintained, therefore, that the effect of the several fruits used in this experiment in lessening the precipitability of the uric acid is due essentially, if not wholly, to the diminished acidity of the urine.

Conclusions.—1. Pears, fresh figs, grapes, dates, and oranges may be taken not only with impunity but with distinct advantage by those who suffer from uric acid calculus and gravel. 2. The beneficial effect, which will be, *cæteris paribus*, in proportion to the amount taken, is due essentially, if not entirely, to the lessened acidity of the urine. 3. Marmalade does not raise the precipitability of the uric acid, though in the quantity likely to be taken it fails to produce the opposite effect, probably because the amount of fruit pulp is insufficient for that purpose.

If it should be suggested that the effects described above are not necessarily those which would be seen in patients suffering from uric acid calculus and gravel, I would reply that I can produce in myself uric acid gravel at will, not for a day or two only but for long periods, by taking a suitable diet for the necessary time, while experiments on a friend led to a similar result. When fruit disagrees—i.e., deranges the digestion—it would, of course, like any other article of food acting in a similar manner, not be prescribed. The experiment is being extended to other varieties of fruit and to some substances other than fruit.

Oxford.

EXPERIENCES OF THE TREATMENT OF THE CANCEROUS CERVIX UTERI BY THE ABDOMINAL ROUTE, WITH PELVIC DISSECTION.[1]

BY ARTHUR J. WALLACE, M.D. EDIN.,
SURGEON TO THE HOSPITAL FOR WOMEN; MEDICAL OFFICER, LADIES CHARITY AND LYING-IN HOSPITAL, LIVERPOOL.

IN the treatment of cancer of the cervix uteri a new phase is looming large on the British gynæcological horizon, and I have thereby been encouraged to bring before you shortly my experiences of the so-called radical operation. The brief time at our disposal does not permit of mention of all the problems involved and I therefore propose to consider chiefly the operative aspects of the subject.

In the first place I venture to remind you of certain anatomical details connected with the pelvic course of the ureters and with the lymphatic vessels passing from the cervix uteri to the glands lying in the pelvic connective tissues. The ureter, the pars pelvica, 12 centimetres in length, extends from the pelvic brim to the bladder. It is subdivided into pelvic and vesical portions, but this is of no importance from the operative point of view. The ureter is inclosed in a sheath of loose connective tissue in which course the special nutritive vessels. These vessels are:—1. The superior ureteric artery, which springs from the ovarian artery as it crosses the ureter in the abdomen and runs downwards, dividing into branches. 2. The inferior ureteric artery or arteries, derived either from the uterine as it crosses the ureter or from the vesical artery. These latter pursue an upward course. Having an independent vascular supply the ureter can be separated from its connexions without ill result provided the vascular sheath be left intact.

The ureter can be readily found by its relation to the internal iliac artery. Division of the infundibulo-pelvic ligament close to the brim results in the formation of a diamond-shaped gap. Gentle stroking of the exposed connective tissue with a finger converts this gap into a cavity which is bounded externally by the artery and internally diastatic activity, led to the same conclusion as the precipitate obtained from it by alcohol. There seemed also no evidence of an increase in the amount of Garrod's urochrome which Klemperer has shown to be an important solvent of uric acid. In judging colorimetrically of the urinary pigments it must not be forgotten that both keeping and increase of acidity darken the urine. The phloroglucine test for the pentoses, applied in the manner recommended by Salkowski, did not show a trustworthy and constant difference of colour between the fruit and non-fruit periods.

---

[1] A paper read before the North of England Obstetrical and Gynæcological Society at Manchester on April 17th, 1905.

It remained, finally, to inquire if the diminished acidity of the urine during the fruit periods sufficed *per se* to account for the *degree* of alteration in the precipitability of the uric acid. On Feb. 22nd–23rd (date period) and on Feb. 25th–27th (non-fruit period) the amount of uric acid was the same and the reaction different. I therefore equalised the latter by adding the necessary quantity of alkali to the more acid urine and of acid to the more alkaline, while the same volume of water was added to other specimens and the precipitability of the uric acid tested in the usual way:—

Experiment 1.

A. (Date period), less acid urine.	B. (Non-fruit period), more acid urine.
March 3rd: 220 c.c. urine (Feb. 22nd to 23rd) 11 c.c water. 7.30 P.M.: 50 c.c. of the mixture. 1 drop acid.	March 3rd: 220 c.c. urine (Feb. 25th to 27th). 11 c.c. NaOH decinormal. 7.30 P.M.: 50 c.c. of the mixture. 1 drop acid.
March 22nd, 10 A.M.: No deposit of uric acid.	March 22nd, 10 A.M.: No deposit of uric acid.

TABLE V.—SHOWING THE GENERAL CONDITION OF THE URINE DURING THE FRUIT AND THE NON-FRUIT PERIODS (SERIES 2).

Period.	Quantity of fruit pulp taken daily.	Date.	Daily quantity of urine.	Specific gravity of diluted urine.	Total (N) daily output.	Uric acid, daily output.	Total acidity determined by phenolphthalein.	Total P_2O_5 daily output.	P_2O_5 as dihydrogen acid, daily output.	Acid needed to start precipitation of uric acid in 48 hours.	Range of temperature during experiments.

* The urine of these two days was mixed and examination made of the mixture.

There was some infiltration of the right broad ligament but none in the utero-sacral folds. Under anæsthesia the mobility of the uterus was found to be considerably greater than at first seemed the case.

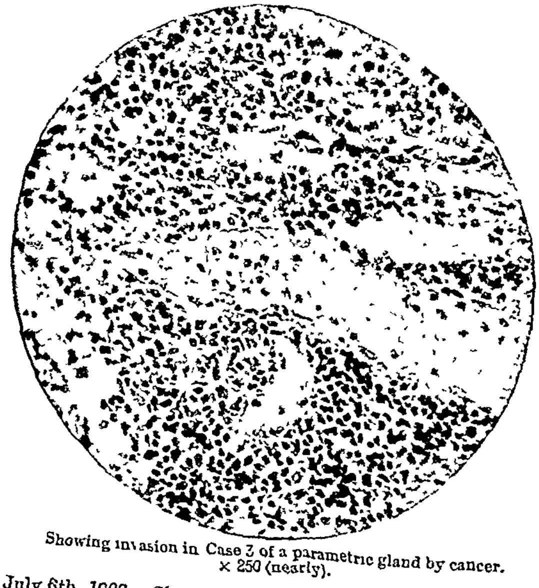
Operation was performed on June 9th, 1903. The ureters were traced forward without previous examination of the cervico-vesical septum—a tactical error. The tunnel of the right ureter passed through the growth in the right broad ligament and its outer surface was involved by it; the ureter, however, shelled out easily. The left was cleared without any sign of disease being found. The bladder was firmly united to the cervix by the growth. As much as possible was scraped off, as at that time I did not feel justified in excising the part of the vesical wall involved. No glands of any kind could be found. Recovery was uninterrupted. The patient was discharged at her own request on the fourteenth day.

CASE 2.—The patient, married, aged 44 years, was admitted to hospital on June 20th, 1903. She had been married 16 years. She had had four children and two abortions. The duration of the symptoms was six months. The local conditions were as follows. The cervix was enlarged, indurated, and irregular; it bled freely on touch The uterus was freely moveable.

Operation was performed on June 23rd, 1903. Both in this and the preceding case the operation was entirely abdominal, the vagina being clamped between two large pairs of compression forceps before division. No trouble was experienced with the ureters. The anterior vaginal wall was sewn to the peritoneum of the bladder; this was found afterwards to limit the capacity of the bladder. Three right and one left iliac glands were found and removed; in size all were apparently normal. The lower end of the abdominal wound suppurated but speedily recovered. On the sixteenth day urine escaped per vaginam. Examination disclosed a small opening on the left of the vaginal apex. The incontinence gradually ceased and had disappeared at the end of six weeks. No evidence of enlargement of the left kidney was discovered at any time. Examination of the glands microscopically did not reveal the presence of cancerous disease. On Oct. 23rd the patient was seen in the out-patient room. A large indurated area was found in the abdominal wall around the cicatrix. From two or three small openings a thin watery fluid escaped. It was evident that the abdominal wound had become infected by cancer cells at the time of operation. A sweeping removal was carried out but recurrence speedily took place and death occurred five months later.

CASE 3.—The patient, aged 36 years, married, had been attended by Dr. W. G. Williams. She was admitted on July 6th, 1903. She had been married 14 years. She had had two children and six abortions. The duration of the symptoms was two years. She was seen a year previously by a well-known gynæcologist who considered that the disease was too extensive for any radical operation. A palliative operation was performed and for some months the patient was much relieved of her symptoms and gained in weight. Gradually the bleeding came on again and the patient sought further relief. The local conditions were as follows. The cervix was represented by an irregular thick mass with a dirty sloughing surface which bled on touch; friability was marked. The vaginal walls were not involved; induration was felt along the bases of both broad ligaments. The mobility of the uterus itself was surprising and it was this circumstance that determined me in giving the patient another chance.

FIG. 1.



Showing invasion in Case 3 of a parametric gland by cancer. × 250 (nearly).

Operation was performed on July 11th. As a preliminary step the cervix was separated from the bladder and as it peeled off freely the operation was proceeded with. The ureters were dissected out with some little difficulty on account of the extreme depth of the pelvis. The thickened right parametrium showed no signs of malignant infiltration and the left was not even indurated. Small iliac glands were removed from both sides. After the usual gauze pack had been placed the sigmoid colon and its mesentery were carefully arranged so as to roof it in. Examination of the glands established the presence of cancer in the right iliac glands. Uninterrupted recovery followed and the patient remained in excellent health without sign of recurrence until June, 1904. She had reported herself regularly every month until that time and although requested to continue doing so she became over-confident and did not reappear until August, when it was ascertained that wide recurrence had taken place at the top of the vaginal canal. Examination under anæsthesia was made and showed such extensive disease that further interference was out of the question.

CASE 4.—The patient, aged 53 years, married, had been attended by Mr. J. Singleton of Kendal. She was admitted on Sept. 10th, 1903. She had been married 20 years but had never been pregnant. The menopause came on at the age of 38 years. The local conditions were as follows. The cervix was small and irregular; the anterior lip was ulcerated and bled on touch. A piece of tissue was removed and examined microscopically; it proved to be squamous-celled carcinoma.

Operation was performed on Sept. 22nd. The omentum was adherent to the anterior half of the pelvic brim. The left appendages were adherent to the floor of the pelvis; these were freed with difficulty. The body of the uterus was small and soft; when grasped with the volsella pus gushed out through a tear caused by the teeth of the forceps. At this stage the disadvantages caused by a layer of abdominal fat, two inches in thickness, and by a very deep pelvic cavity impressed themselves forcibly on me. The difficulty was increased by the impossibility of drawing the uterus up, on account of infiltration at the base of the left broad ligament. The patient took the anæsthetic badly and strained a good deal. This was the first case in which an internal iliac artery was ligatured. The left artery was doubly ligatured and divided between the ligatures; the right could not be satisfactorily exposed, and the uterine artery was therefore ligatured at its origin. The infiltration of the left broad ligament was continued into the utero-sacral fold of the same side and during the clearing out of the latter free venous bleeding occurred, easily checked, however, by pressure. Adrenalin chloride solution was applied to make certain that it was permanently stopped. There was no difficulty in freeing the ureters, bladder, and connective tissues. No glands were to be found. The patient's condition was now a serious one. The ureters were dealt with as usual and, be it noted, they were quite intact. The abdomen was then quickly closed. The after-condition was never satisfactory, although the patient rallied well. She did not sleep, she talked incessantly, and passed very little urine. During the first 48 hours only four ounces were voided, but this amount gradually increased during the following three days. In spite of this the condition steadily grew worse, nothing gave sleep, and the patient slowly sank and died, presumably from sepsis.

CASE 5.—The patient, aged 35 years, married, had been attended by Mr. T. H. Summerhill of Rhyl; she was admitted on Oct. 14th, 1903. The duration of the symptoms was four months. The local conditions were as follows. The cervix was excavated; there was infiltration of the anterior wall which apparently involved the bladder. The body of the uterus was only slightly moveable. The left broad ligament was thickened and fixed. The patient was kept in bed for usually by the ureter. If the posterior lamella of the broad ligament be hooked up by a finger placed behind it, the ureter will be found running across the palmar surface. From this point its course is mainly forward through the base of the broad ligament at a varying distance from the cervix. It may hug the latter closely or remain at a distance of one and a half inches. In nearly all cases it passes through a well-defined fibrous tunnel to the walls of which it is connected by loose cellular tissue that readily permits the ureter to be shelled out of its tunnel. Even when the broad ligament is infiltrated by cancer it is sometimes possible to turn the ureter with its vascular sheath cleanly out of a tunnel, the outer surface of which is intimately attached to the diseased tissues.

The lymphatics passing from the mucous and muscular coats of the cervix finally unite into two or three main trunks which open into one or more small glands situated in the parametric tissues close to the cervix. Each of these trunks has a diameter equal to that of the uterine artery and is provided with valves the concavity of which is directed outwards. Under pressure these valves become incompetent. After passing through the parametric glands the main lymphatic trunks are joined by the lymphatics from the upper part of the vagina. They then accompany the uterine artery until they terminate in the glands lying along the internal iliac artery. The largest gland lies in the bifurcation of the common iliac and one or more are situated beneath it, whilst below these, in close relationship to the branches of the internal iliac artery, lies the gland which receives the lymph channels from the middle portion of the vagina which course upwards with the vaginal artery. Sometimes a gland is found near the origin of this set of vessels in close relation to the recto-vaginal septum. The cervical lymphatics communicate with the gland lying immediately beneath the entrance to the obturator canal and also with the sacral glands which lie on the antero-lateral aspect of the sacrum. Unless enlargement of these glands exists recognition by vaginal, rectal, or abdominal palpation is not possible. Enlargement of a gland does not necessarily imply that it is cancerous, whilst a cancerous gland is not necessarily enlarged. A notable point is that in quite a number of cases no glands are to be found, normal or otherwise. Döderlein, for example, was unable to find glands in eight out of 26 cases. In my own cases careful search failed to reveal them in four out of ten cases. On the other hand, Wertheim found glands in every one of 80 cases.

Opportunity may be taken at this point to mention that recent investigations have shown that cancerous extension may take place along the lymphatics of the branches of the sacral plexus of nerves. Cancer cells have been found invading peri-, epi-, and endo-neuria, in some cases only fortunately, otherwise operative interference in cancer of the cervix would be wellnigh hopeless.

The abdomen is opened by an incision extending from the pubes to the umbilicus and the patient is placed in the Trendelenburg position, without the aid of which the operation would be impossible. All free intestine is cleared out of the pelvis and retained in the upper part of the abdomen by careful packing with a sterilised towel or pad. Visual and digital exploration of the pelvic organs follows. It is especially advisable to examine carefully the cervico-vesical septum, the utero-sacral folds, and the regions which the pelvic glands occupy. The first is of greatest importance, as while slight involvement merely modifies the procedure somewhat a greater degree would call for abandonment of the operation.

As a rule, the mobility of the uterus proves greater than appears to be the case bimanually and when the assistant makes traction upon it by means of a pair of Museaux forceps the infundibulo-pelvic and round ligaments are in turn readily made tense. With this help each of these ligaments is secured by double ligatures placed as close to the pelvic brim as possible and the portions lying between the ligatures are divided with scissors. The four gaps thus created are connected by division of the intervening peritoneal areas, the incision which passes from one round ligament to its fellow coursing along the bottom of the utero-vesical pouch. The cut peritoneal edges retract inwards and outwards, leaving exposed the lateral and anterior borders of the parametric tissues. The uterus being drawn upwards and backwards, separation of the bladder from the cervix and vagina is effected with the finger. The uterus is then drawn forwards and attention is directed to the ureters. Generally, the left ureter is first exposed and separated from the internal iliac artery and the connective tissues on its outer aspect; this allows the ureter to be drawn gently inwards. The internal iliac artery is dissected bare of investing tissues and ligatured about its middle. The same steps are carried out on the opposite side, so that under ordinary conditions it is now possible to work freely in the pelvic connective tissues with the minimum of bleeding. Whether one proceeds on the right side or the left is a matter of indifference; I generally select the left.

The left ureter is traced forwards, care being taken not to separate it from the posterior lamella of the broad ligament until it actually turns forward in earnest. With the help of two pairs of dissecting forceps the ureter is shelled out of its tunnel, the peritoneum of the broad ligament being pushed inwards during the process and the connective tissues being torn through in a direction upwards and outwards, so that when the point of entry into the bladder wall is reached the ureter can be simply lifted up and carried out to the pelvic brim. This cannot be satisfactorily done until the parametric tissues have been dissected off the walls of the pelvis and bladder. Beginning on the pelvic wall, partly with the finger, partly with dissecting forceps, the tissues are peeled and scraped off. Theoretically, the aim is absolutely to denude the pelvic fascia; practically, one gets away as much as possible. Sometimes an enlarged obturator gland is encountered; occasionally a branch of the uterine artery is wounded and spouts, despite the ligature of the parent trunk. As the dissection passes more deeply the uterine artery is again encountered, lying close to the pelvic wall, and for safety it is ligatured close to its origin before being divided and swept inwards with the connective tissues. These are being steadily heaped up around the uterus and they are added to by separation of the broad ligament tissues from the bladder. The finger can now be pushed deeply down beneath the parametrium till it lies on the vagina which in its turn is freely separated. These procedures are repeated on the right side and at their termination both ureters are free, the anterior and lateral parametric tissues have been freed and swept inwards, and the interior and lateral aspects of the vagina for its superior half are free. A semicircular incision through the peritoneum is now made across the bottom of the pouch of Douglas, extending from the right to the left infundibulo-pelvic ligament. Through this the posterior wall of the vagina is separated from the rectum and the tissues in the utero-sacral folds are dislodged and added to the central mass. The uterus is now quite free and can be pushed down the vaginal tube until the upper half of the latter is inverted within the lower. The abdominal wound is temporarily closed and the patient placed in the lithotomy position. The cervix, grasped by a pair of volsella, is drawn down until the vagina is almost completely inverted. The vaginal wall is carefully cleansed and then cut through by a circular sweep of the knife. It only remains to pull out the uterus and push a temporary pad of gauze in the reinverted vagina. The Trendelenburg position is resumed, the abdominal wound reopened, and all available peritoneum is used to cover over raw surfaces. If possible the ureters are secured to the lateral pelvic walls by peritoneal flaps, but, as a rule, pressure of the light gauze pack with which the pelvic cavity is filled is sufficient to effect this. The lower end of the pack is brought out per vaginam, the intestines are rearranged, and the abdomen is finally closed.

It should be mentioned that in the first eight cases the vagina was divided from the abdomen. This method, however, seems to carry with it the risks of septic infection and of cancerous inoculation of sound tissues. With the combined method the chances of either occurring are much diminished. No forceps, however powerful, seem to be strong enough to clamp satisfactorily the vagina before dividing it from the abdomen.

CASE 1.—The patient, married, aged 49 years, who had been attended by Mr. W. J. R. Dunn, was admitted to the Hospital for Women on June 6th, 1903: She had been married 26 years. She had had one child and three abortions; the menopause occurred at 41 years of age. The duration of the symptoms was seven months; at their onset the patient consulted a medical man who did not make an examination but suggested that she "should go home and prepare to die"—advice which certainly offers ground for reflection. Later she consulted Mr. Dunn who sent her into hospital. The local conditions were as follows. The cervix was excavated and the mobility of the uterus was diminished.

There was some infiltration of the right broad ligament but none in the utero-sacral folds. Under anæsthesia the mobility of the uterus was found to be considerably greater than at first seemed the case.

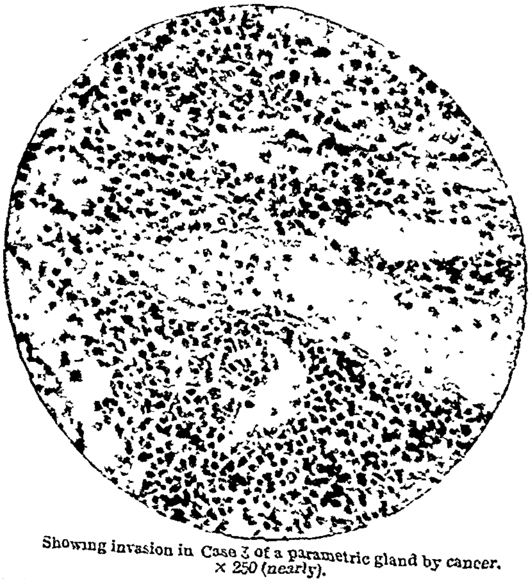
Operation was performed on June 9th, 1903. The ureters were traced forward without previous examination of the cervico-vesical septum—a tactical error. The tunnel of the right ureter passed through the growth in the right broad ligament and its outer surface was involved by it; the ureter, however, shelled out easily. The left was cleared without any sign of disease being found. The bladder was firmly united to the cervix by the growth. As much as possible was scraped off, as at that time I did not feel justified in excising the part of the vesical wall involved. No glands of any kind could be found. Recovery was uninterrupted. The patient was discharged at her own request on the fourteenth day.

CASE 2.—The patient, married, aged 44 years, was admitted to hospital on June 20th, 1903. She had been married 16 years. She had had four children and two abortions. The duration of the symptoms was six months. The local conditions were as follows. The cervix was enlarged, indurated, and irregular; it bled freely on touch. The uterus was freely moveable.

Operation was performed on June 23rd, 1903. Both in this and the preceding case the operation was entirely abdominal, the vagina being clamped between two large pairs of compression forceps before division. No trouble was experienced with the ureters. The anterior vaginal wall was sewn to the peritoneum of the bladder; this was found afterwards to limit the capacity of the bladder. Three right and one left iliac glands were found and removed; in size all were apparently normal. The lower end of the abdominal wound suppurated but speedily recovered. On the sixteenth day urine escaped per vaginam. Examination disclosed a small opening on the left of the vaginal apex. The incontinence gradually ceased and had disappeared at the end of six weeks. No evidence of enlargement of the left kidney was discovered at any time. Examination of the glands microscopically did not reveal the presence of cancerous disease. On Oct. 23rd the patient was seen in the out-patient room. A large indurated area was found in the abdominal wall around the cicatrix. From two or three small openings a thin watery fluid escaped. It was evident that the abdominal wound had become infected by cancer cells at the time of operation. A sweeping removal was carried out but recurrence speedily took place and death occurred five months later.

CASE 3.—The patient, aged 36 years, married, had been attended by Dr. W. G. Williams. She was admitted on July 6th, 1903. She had been married 14 years. She had two children and six abortions. The duration of the symptoms was two years. She was seen a year previously by a well-known gynæcologist who considered that the disease was too extensive for any radical operation. A palliative operation was performed and for some months the patient was much relieved of her symptoms and gained in weight. Gradually the bleeding came on again and the patient sought further relief. The local conditions were as follows. The cervix was represented by an irregular thick mass with a dirty sloughing surface which bled on touch; friability was marked. The vaginal walls were not involved; induration was felt along the bases of both broad ligaments. The mobility of the uterus itself was surprising and it was this circumstance that determined me in giving the patient another chance.

FIG. 1.



Showing invasion in Case 3 of a parametric gland by cancer. × 250 (nearly).

Operation was performed on July 11th. As a preliminary step the cervix was separated from the bladder and as it peeled off freely the operation was proceeded with. The ureters were dissected out with some little difficulty on account of the extreme depth of the pelvis. The thickened right parametrium showed no signs of malignant infiltration and the left was not even indurated. Small iliac glands were removed from both sides. After the usual gauze pack had been placed the sigmoid colon and its mesentery were carefully arranged so as to roof it in. Examination of the glands established the presence of cancer in the right iliac glands. Uninterrupted recovery followed and the patient remained in excellent health without sign of recurrence until June, 1904. She had reported herself regularly every month until that time and although requested to continue doing so she became over-confident and did not reappear until August, when it was ascertained that wide recurrence had taken place at the top of the vaginal canal. Examination under anæsthesia was made and showed such extensive disease that further interference was out of the question.

CASE 4.—The patient, aged 53 years, married, had been attended by Mr. J. Singleton of Kendal. She was admitted on Sept. 10th, 1903. She had been married 20 years but had never been pregnant. The menopause came on at the age of 38 years. The local conditions were as follows. The cervix was small and irregular; the anterior lip was ulcerated and bled on touch. A piece of tissue was removed and examined microscopically; it proved to be squamous-celled carcinoma.

Operation was performed on Sept. 22nd. The omentum was adherent to the anterior half of the pelvic brim. The left appendages were adherent to the floor of the pelvis; these were freed with difficulty. The body of the uterus was small and soft; when grasped with the volsella pus gushed out through a tear caused by the teeth of the forceps. At this stage the disadvantages caused by a layer of abdominal fat, two inches in thickness, and by a very deep pelvic cavity impressed themselves forcibly on me. The difficulty was increased by the impossibility of drawing the uterus up, on account of infiltration at the base of the left broad ligament. The patient took the anæsthetic badly and strained a good deal. This was the first case in which an internal iliac artery was ligatured. The left artery was doubly ligatured and divided between the ligatures; the right could not be satisfactorily exposed, and the uterine artery was therefore ligatured at its origin. The infiltration of the left broad ligament was continued into the utero-sacral fold of the same side and during the clearing out of the latter free venous bleeding occurred, easily checked, however, by pressure. Adrenalin chloride solution was applied to make certain that it was permanently stopped. There was no difficulty in freeing the ureters, bladder, and connective tissues. No glands were to be found. The patient's condition was now a serious one. The ureters were dealt with as usual and, be it noted, they were quite intact. The abdomen was then quickly closed. The after-condition was never satisfactory, although the patient rallied well. She did not sleep, she talked incessantly, and passed very little urine. During the first 48 hours only four ounces were voided, but this amount gradually increased during the following three days. In spite of this the condition steadily grew worse, nothing gave sleep, and the patient slowly sank and died, presumably from sepsis.

CASE 5.—The patient, aged 35 years, married, had been attended by Mr. T. H. Summerhill of Rhyl; she was admitted on Oct. 14th, 1903. The duration of the symptoms was four months. The local conditions were as follows. The cervix was excavated; there was infiltration of the anterior wall which apparently involved the bladder. The body of the uterus was only slightly moveable. The left broad ligament was thickened and fixed. The patient was kept in bed for usually by the ureter. If the posterior lamella of the broad ligament be hooked up by a finger placed behind it, the ureter will be found running across the palmar surface. From this point its course is mainly forward through the base of the broad ligament at a varying distance from the cervix. It may hug the latter closely or remain at a distance of one and a half inches. In nearly all cases it passes through a well-defined fibrous tunnel to the walls of which it is connected by loose cellular tissue that readily permits the ureter to be shelled out of its tunnel. Even when the broad ligament is infiltrated by cancer it is sometimes possible to turn the ureter with its vascular sheath cleanly out of a tunnel, the outer surface of which is intimately attached to the diseased tissues.

The lymphatics passing from the mucous and muscular coats of the cervix finally unite into two or three main trunks which open into one or more small glands situated in the parametric tissues close to the cervix. Each of these trunks has a diameter equal to that of the uterine artery and is provided with valves the concavity of which is directed outwards. Under pressure these valves become incompetent. After passing through the parametric glands the main lymphatic trunks are joined by the lymphatics from the upper part of the vagina. They then accompany the uterine artery until they terminate in the glands lying along the internal iliac artery. The largest gland lies in the bifurcation of the common iliac and one or more are situated beneath it, whilst below these, in close relationship to the branches of the internal iliac artery, lies the gland which receives the lymph channels from the middle portion of the vagina which course upwards with the vaginal artery. Sometimes a gland is found near the origin of this set of vessels in close relation to the recto-vaginal septum. The cervical lymphatics communicate with the gland lying immediately beneath the entrance to the obturator canal and also with the sacral glands which lie on the antero-lateral aspect of the sacrum. Unless enlargement of these glands exists recognition by vaginal, rectal, or abdominal palpation is not possible. Enlargement of a gland does not necessarily imply that it is cancerous, whilst a cancerous gland is not necessarily enlarged. A notable point is that in quite a number of cases no glands are to be found, normal or otherwise. Döderlein, for example, was unable to find glands in eight out of 26 cases. In my own cases careful search failed to reveal them in four out of ten cases. On the other hand, Wertheim found glands in every one of 80 cases.

Opportunity may be taken at this point to mention that recent investigations have shown that cancerous extension may take place along the lymphatics of the branches of the sacral plexus of nerves. Cancer cells have been found invading peri-, epi-, and endo-neuria, in some cases only fortunately, otherwise operative interference in cancer of the cervix would be wellnigh hopeless.

The abdomen is opened by an incision extending from the pubes to the umbilicus and the patient is placed in the Trendelenburg position, without the aid of which the operation would be impossible. All free intestine is cleared out of the pelvis and retained in the upper part of the abdomen by careful packing with a sterilised towel or pad. Visual and digital exploration of the pelvic organs follows. It is especially advisable to examine carefully the cervico-vesical septum, the utero-sacral folds, and the regions which the pelvic glands occupy. The first is of greatest importance, as while slight involvement merely modifies the procedure somewhat a greater degree would call for abandonment of the operation.

As a rule, the mobility of the uterus proves greater than appears to be the case bimanually and when the assistant makes traction upon it by means of a pair of Museaux forceps the infundibulo-pelvic and round ligaments are in turn readily made tense. With this help each of these ligaments is secured by double ligatures placed as close to the pelvic brim as possible and the portions lying between the ligatures are divided with scissors. The four gaps thus created are connected by division of the intervening peritoneal areas, the incision which passes from one round ligament to its fellow coursing along the bottom of the utero-vesical pouch. The cut peritoneal edges retract inwards and outwards, leaving exposed the lateral and anterior borders of the parametric tissues. The uterus being drawn upwards and backwards, separation of the bladder from the cervix and vagina is effected with the finger. The uterus is then drawn forwards and attention is directed to the ureters. Generally, the left ureter is first exposed and separated from the internal iliac artery and the connective tissues on its outer aspect; this allows the ureter to be drawn gently inwards. The internal iliac artery is dissected bare of investing tissues and ligatured about its middle. The same steps are carried out on the opposite side, so that under ordinary conditions it is now possible to work freely in the pelvic connective tissues with the minimum of bleeding. Whether one proceeds on the right side or the left is a matter of indifference; I generally select the left.

The left ureter is traced forwards, care being taken not to separate it from the posterior lamella of the broad ligament until it actually turns forward in earnest. With the help of two pairs of dissecting forceps the ureter is shelled out of its tunnel, the peritoneum of the broad ligament being pushed inwards during the process and the connective tissues being torn through in a direction upwards and outwards, so that when the point of entry into the bladder wall is reached the ureter can be simply lifted up and carried out to the pelvic brim. This cannot be satisfactorily done until the parametric tissues have been dissected off the walls of the pelvis and bladder. Beginning on the pelvic wall, partly with the finger, partly with dissecting forceps, the tissues are peeled and scraped off. Theoretically, the aim is absolutely to denude the pelvic fascia; practically, one gets away as much as possible. Sometimes an enlarged obturator gland is encountered; occasionally a branch of the uterine artery is wounded and spouts, despite the ligature of the parent trunk. As the dissection passes more deeply the uterine artery is again encountered, lying close to the pelvic wall, and for safety it is ligatured close to its origin before being divided and swept inwards with the connective tissues. These are being steadily heaped up around the uterus and they are added to by separation of the broad ligament tissues from the bladder. The finger can now be pushed deeply down beneath the parametrium till it lies on the vagina which in its turn is freely separated. These procedures are repeated on the right side and at their termination both ureters are free, the anterior and lateral parametric tissues have been freed and swept inwards, and the interior and lateral aspects of the vagina for its superior half are free. A semicircular incision through the peritoneum is now made across the bottom of the pouch of Douglas, extending from the right to the left infundibulo-pelvic ligament. Through this the posterior wall of the vagina is separated from the rectum and the tissues in the utero-sacral folds are dislodged and added to the central mass. The uterus is now quite free and can be pushed down the vaginal tube until the upper half of the latter is inverted within the lower. The abdominal wound is temporarily closed and the patient placed in the lithotomy position. The cervix, grasped by a pair of volsella, is drawn down until the vagina is almost completely inverted. The vaginal wall is carefully cleansed and then cut through by a circular sweep of the knife. It only remains to pull out the uterus and push a temporary pad of gauze in the reinverted vagina. The Trendelenburg position is resumed, the abdominal wound reopened, and all available peritoneum is used to cover over raw surfaces. If possible the ureters are secured to the lateral pelvic walls by peritoneal flaps, but, as a rule, pressure of the light gauze pack with which the pelvic cavity is filled is sufficient to effect this. The lower end of the pack is brought out per vaginam, the intestines are rearranged, and the abdomen is finally closed.

It should be mentioned that in the first eight cases the vagina was divided from the abdomen. This method, however, seems to carry with it the risks of septic infection and of cancerous inoculation of sound tissues. With the combined method the chances of either occurring are much diminished. No forceps, however powerful, seem to be strong enough to clamp satisfactorily the vagina before dividing it from the abdomen.

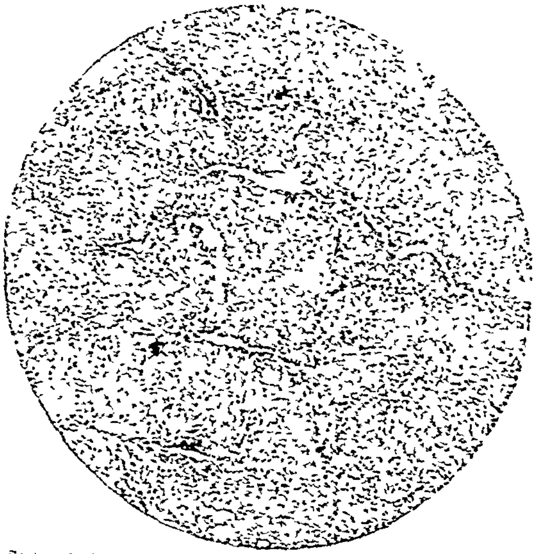
CASE 1.—The patient, married, aged 49 years, who had been attended by Mr. W. J. R. Dunn, was admitted to the Hospital for Women on June 6th, 1903. She had been married 26 years. She had had one child and three abortions; the menopause occurred at 41 years of age. The duration of the symptoms was seven months; at their onset the patient consulted a medical man who did not make an examination but suggested that she "should go home and prepare to die"—advice which certainly offers ground for reflection. Later she consulted Mr. Dunn who sent her into hospital. The local conditions were as follows. The cervix was excavated and the mobility of the uterus was diminished.

1904, when all the symptoms suggestive of recurrence appeared and the patient gradually sank.

CASE 9.—The patient, aged 54 years, was admitted on May 27th, 1904. She had been married for 18 years but had never been pregnant. The menopause occurred at 49 years of age. The symptoms had been of three months' duration. The following were the local conditions: the cervix was excavated; there was marked induration in the left broad ligament interfering considerably with the mobility of the uterus; the utero sacral folds were apparently free. On May 28th the cervical ulcer was curetted, after which a 60 per cent. solution of zinc chloride was applied.

On June 7th operation was proceeded with. The left side of the bladder was adherent to, and dragged backwards by, the sigmoid colon and there were numerous omental adhesions to the bladder. After these had been dealt with and the pelvis emptied of intestine it could be seen that there were large deposits of fat in the pelvic connective tissues. As usual, the mass in the left broad ligament was much larger than had previously appeared; it was adherent to the bladder and involved the utero-vesical septum. The right ureter was dealt with but as I wished to run no risks with it the uterine artery alone was tied. The left internal iliac was then ligatured, a mass of enlarged glands cleared out, and an attempt made to expose the ureter. This was very difficult and ultimately part of it had to be traced from its anterior end. The whole of the posterior wall of the bladder was resected with the exception of two tongues carrying the ureteral openings and the bladder wound was sutured with catgut. The remaining attachments of the uterus were freed, the vagina was separated, and removal was carried out per vaginam. To do this incision of the vagina was necessary. The operation was concluded in the usual way and a drainage-tube was placed in the bladder. The patient recovered steadily, but on the sixteenth day urine escaped per vaginam. The bladder remained quite sound, but it has been ascertained that the left ureter sloughed; the result has been that a uretero-vaginal fistula has formed. Two attempts have been made to close it, but a small opening still exists in place of one that easily admitted the finger-tip. This patient is still alive and well. The left iliac glands were extensively involved by cancer.

FIG. 3.

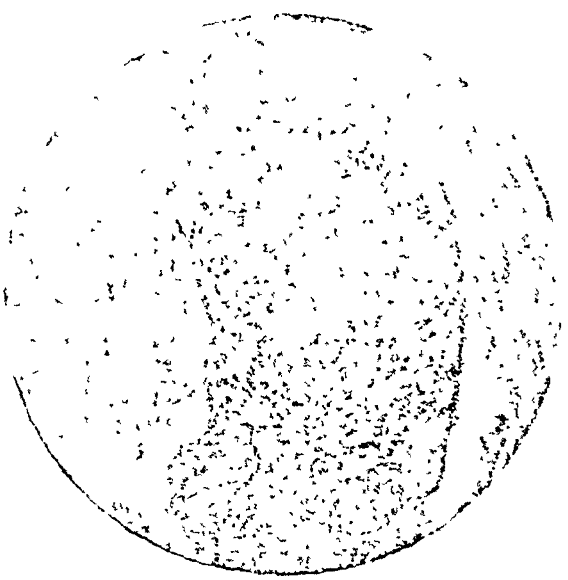


Section in Case 9 of cancerous left iliac gland, showing degenerating lymphoid tissue surrounded by cancer cells. × 45 (nearly).

CASE 10.—The patient, aged 43 years, was admitted on Jan. 7th, 1905. She had been married 25 years and had had 13 children. The duration of the symptoms was eight months. The local conditions were as follows. The cervix was excavated and the uterus was freely moveable; no extension beyond it could be discovered.

The operation was carried out on Jan. 14th. The pelvic connective tissues appeared to be quite free from disease and as there was but little oozing of blood the internal iliacs were not tied. With this exception the procedure did not vary from the description given above. The uterine arteries were ligatured at their origins and a large vesical artery required tying on the left side. On the left iliac vessels a large gland measuring one and a half inches in length by half an inch in thickness was removed. A small one lay along the right artery. Search for others was futile. This operation was by far the most easy of the whole ten but most unfortunately the patient died from sepsis on the sixth day. At the necropsy general peritonitis was found.

FIG. 4.



Section in Case 10 of cancerous left iliac gland. × 200 (nearly).

Of the ten operations three were incomplete, one because the patient's condition necessitated speedy termination of the operation and two because of extension of the disease to the bladder wall. It has been borne in upon me that ruthless excision is necessary for the success of this operation. Involvement of the bladder implies either abandonment of the operation or free removal of the affected area. Involvement of the ureters in a cancerous broad ligament calls for resection with fresh implantation into the bladder.

With regard to the pelvic connective tissues any attempt to remove them cleanly must necessarily be out of the question. Even in lean individuals a surprising quantity of fatty tissue is found beneath the pelvic peritoneum and complete removal of it is a task better suited for the dissecting rather than the operating room. In most cases I was struck by the small amount of tissue contained in the utero-sacral folds; in no instance was anything resembling a gland turned out of them, nor could any sacral glands be discovered. Perhaps this is not surprising, since in no single one of the cases was any induration behind the uterus detected previously to operation. In this connexion it is interesting to bear in mind the dictum of Wertheim: "Infiltration does not necessarily imply carcinoma, nor does a soft condition exclude it."

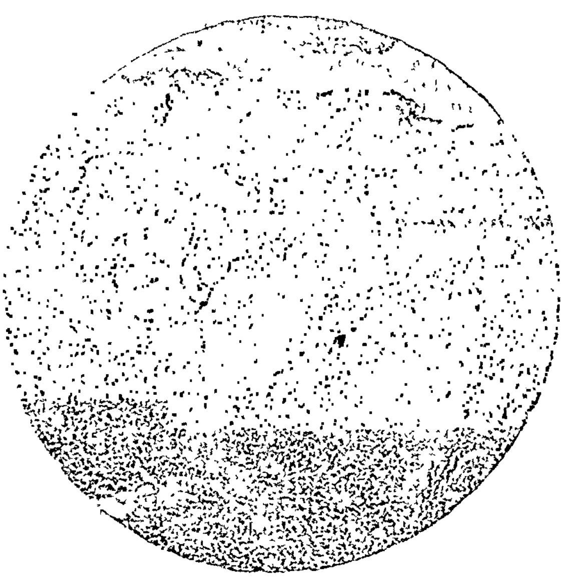
The modes of advance of cancer are either by direct continuation of growth from the cervix into the parametrium, or, the cervix being surrounded by intact connective tissues, the metastases are found principally in the glands, or there may be a combination of both these modes. Kundrat has investigated the condition of the parametrium by serial section cutting in 80 cases and he found it was affected in 55 per cent. of them: on one side only in 23·75 per cent., on both in 31·25 per cent. In 22 cases the parametrium alone was diseased, the glands being normal; in eight the parametrium was uninvolved, whilst the glands were diseased. In a number of cases in which the parametrium was indurated no sign of cancer could be detected and, inversely, disease was discovered in soft parametria. As causes of non-cancerous infiltration Kundrat suggests changes in the vessels—proliferation of the intima, closure of the lumen, and thrombosis—which probably have some relation to the new growth. The accompanying exudation and a week, during which time hot douches and glycerine pledgets were employed. At the end of the week the mobility of the uterus had considerably increased, so I decided to explore the condition of matters.

Operation was performed on Oct. 20th. The peritoneum at the bottom of the utero-vesical pouch was puckered and adherent to the underlying growth. Both internal iliac arteries were ligatured. The right ureter was freed without trouble; the left was shelled out of a mass of carcinoma in the left broad ligament. As a matter of fact, the tunnel only was adherent to the growth, the loose tissue surrounding the ureter itself being apparently unaffected and the ureter when freed was seen to be covered by a thin layer of fat in which the ramifying vessels were distictly visible. To ascertain the extent of bladder involvement an opening was made in the viscus and its cavity was explored by the finger. The infiltration was too widespread to justify any resection of the bladder, so the wound was closed. All disease that could be cut and scraped away was removed and after the usual peritoneal stitching the abdomen was closed. No glands were found. Recovery was normal. The patient was discharged on Nov. 14th, healing being complete except for the small crateriform ulcer at the summit of the vagina. The disease steadily advanced, metastases formed in the liver, and death took place on Jan. 25th, 1904.

CASE 6.—The patient, aged 50 years, married, had been attended by Dr. J. D. R. Munro of Nantwich. She had been married 20 years. She had had eight children and two abortions. The duration of the symptoms was four and a half months. The local conditions were as follows. The cervix was indurated; the os admitted the tip of the forefinger which passed into an irregular excavated cavity. There was some induration on the left of the uterus. The uterus was perfectly moveable.

Operation was performed on Nov. 7th. Both internal iliac arteries were ligatured. The ureters and bladder were freed. The vagina was divided with a knife, the upper end being guarded with a gauze pad and the whole being lifted out together. A gauze pack was placed in the lower vaginal end. A large mass of glandular tissues was found immediately below the right obturator canal. A few small glands in a similar position were found on the left side. None were discovered along the iliac vessels of either side, although one was found in the base of the right broad ligament. Recovery was normal. This patient is still alive and well. The right obturator gland was found to be invaded by cancer.

FIG. 2.



Section in Case 6 of cancerous obturator gland of the right side. × 45 (nearly).

CASE 7.—The patient, aged 55 years, under the care of Dr. R. Lucins Wood of Huyton, was admitted on Nov. 16th, 1903. She had been married for 35 years, had had 13 children, and had aborted twice. The menopause occurred at 44 years of age. The symptoms had lasted for three or four months. She had lost much blood and looked blanched. The cervix was excavated and the uterus was moveable. She was operated upon on Nov. 21st, 1903.

The case is an example of the difficulty that may be encountered during the performance of this operation. The general condition of the patient was bad; the subcutaneous fat was dirty looking, œdematous, and friable; and the rectus muscle resembled the pale muscle of the rabbit. The preliminary steps were carried out in the usual manner, and then occurred trouble with the anæsthetic. The patient took both chloroform and ether badly, fluid collected in the trachea, and cyanosis became marked. After some improvement the pelvic connective tissues were opened up and then the venous plexuses in the broad ligaments were seen to be enormously congested. Veins one centimetre in diameter twined and twisted in great bunches and concealed only too effectually the underlying ureters and vessels. After some manipulation the left internal iliac artery was found and tied, but during the tracing forward of the ureter one of these veins was wounded. The pelvis was immediately flooded with blood but the bleeding was checked by packing with a sterilised towel. Its withdrawal was followed by similar alarming hæmorrhage and it was only at the slow and careful removal of the pack for the third time that the bleeding point was secured. The large veins had now collapsed and the freeing of the ureter was accomplished. Rather than risk a similar occurrence on the right side I contented myself with ligaturing down the broad ligament, removed the uterus, and sent the patient back to bed as rapidly as possible. She was very much collapsed, never rallied, and died in 18 hours.

CASE 8.—The patient, aged 48 years, who had been under the care of Dr. A. MacLennan of Runcorn, was admitted on Nov. 20th, 1903. She had been married for six years and had had two children. The menopause had occurred at 44 years of age. The symptoms had lasted for four and a half months. The cervix was excavated; the uterus was slightly moveable laterally, but it could not be drawn down to the vaginal ostium. After a week's rest and treatment the mobility of the uterus was found to be increased, but there was now felt clearly a large mass in the right broad ligament. This case was not one in which vaginal hysterectomy could be carried out, but I decided to attempt the abdominal operation as the patient was very anxious to have something done.

The operation was performed on Dec. 1st, 1903. The bladder was found to be adherent to the cervix, but the connexion was tough, suggesting inflammatory rather than malignant tissue. After dealing with the internal iliac arteries and the left ureter the mass on the right side of the uterus was investigated. Its size was about that of a bantam's egg and it was firmly attached to the uterus and to the bladder. The right ureter dived into its centre and careful dissection was required to free it. After tedious and difficult work, involving much handling of the ureter, that tube was cleared, but unfortunately minus its nutritive vessels. Next, the muscular wall of the bladder to which the malignant lump adhered was stripped off the underlying mucous membrane of the bladder and cut away. The mucous membrane bulged, thinned, and threatened to burst under the pressure of the little urine in the bladder, but the catastrophe was averted by the immediate use of the catheter. The healthy edges of bladder muscle were then sutured together. Shortly afterwards, in drawing the fundus uteri to the left, a loud crack was heard, caused by a split between body and cervix. The opening rapidly increased but no discharge was allowed to ooze up. However, the uterus and most of the cervix soon broke off, leaving the right-sided mass still attached to the vagina. The removal of this concluded a long operation. No glands were found. The recovery was uneventful until the seventh day, when urine escaped from the vagina. On Jan. 4th, 1904, two sloughs were found lying in the upper end of the vagina. One resembled a piece of tube laid open along its long axis; the other was indefinite in shape. It was ascertained that the urine was coming down a funnel-shaped opening on the right of the upper end of the vagina. Progress was good until the 27th, when a rigor occurred with a temperature of 103·8° F., and pus was found in the urine. The disturbance passed off and the patient returned home on Feb. 3rd, urine still being passed per vaginam. The incontinence ceased a few weeks after the patient's return home. The general health was fair until the beginning of June, to the asylum on May 21st, 1902. The family history, as given, was normal as regarded nervous disorders except that one sister suffered from "fits." The personal history was also normal. The patient had been healthy in mind and body until she got a severe attack of influenza at the close of December, 1901. Since that time she had not been quite well but was able to do her work up to a date two months prior to admission. No cause for the present attack was known apart from influenza. During the two months preceding admission she was low-spirited, lacrymose, and hypochondriacal. Recently she had been maniacal, with the usual symptoms. The following is a summary of the medical certificate of admission: "Lying in bed, shouting and muttering incoherently; mistakes of identity; some exaltation; insomnia; refusal of food, saying same was poisoned." On admission the patient was restless, resistive, hostile, and destructive; she was filthy in habits, noisy, unconscious of time and place, had delusions of persecution, hallucinations of vision, mistakes of identity, and much exaltation. Physically she was well nourished and powerful. Her face, hands, and feet were very cyanosed. The pulse was 88, the respirations were 16, and there was aortic regurgitation. There was tremor of the lips, the tongue, and the hands. Speech was tremulous. The pupils were equal and of normal contour; there was no reaction to light and they were sluggish to accommodation. There were nebulæ about both corneæ. The knee-jerks were exaggerated. She was certified five days after admission by me as being in a state of "acute dementia, muttering unintelligibly, lying on the floor, moving constantly and aimlessly, resisting strongly, filthy in habits, destructive, refusing food. Physically well nourished and strong." The further history was as follows. She continued noisy, restless, and resistive. Sordes appeared on the lips. The day before death there were moist sounds over the lungs; the pulse was quick and irregular; the temperature was not raised. She died on May 29th (eight days after admission).

Necropsy.—A post-mortem examination was held the next morning. The only morbid appearances were as follows. The dura mater was adherent to the skull cap in front; there was slight opacity of the pia arachnoid over the sulci. The left ventricle was hypertrophied, the myocardium was friable, and the aortic valves were thickened and atheromatous. The pharynx and trachea were very congested. The liver showed old nutmeg change. Nothing else abnormal was noted in the brain or elsewhere. The weight of the brain was (probably before stripping and unopened, but not stated) 48 ounces; the grey and white matter was of good consistence. The tangential fibres of the outermost layer of the cortex cerebri were found to be degenerated. A blood-serum tube inoculated with blood from the heart showed growth on the third day. A subculture from this tube was pronounced by Dr. D. N. Nabarro to be pure growth of the bacillus diphtheriæ.[1]

CASE 2.—The patient was a single man, aged 21 years. It was his first attack and he was admitted to the asylum on Feb. 21st, 1905. The family history was as follows. The mother was epileptic and her father was "peculiar"; nothing further abnormal was ascertained. The patient's personal history was good. The present illness dated back to a recent attack of influenza. The present attack was of about one month's duration; the acuter phase had lasted one week. He had taken food badly; sleep was deficient; he had constipation, increasing incoherence, with hallucinations, and restlessness. The following is a summary of his medical certificate of admission: "Not a moment quiet; appears not to understand; takes no notice; incessant incoherent talk; refusal of food; insomnia." On admission his temperature was 101° F. (thereafter it became normal, but on March 3rd it rose to 100·2° and remained at between 99° and 100° until the morning of death when it was 101°). There was great physical reduction; the tongue was coated and tremulous; there was marked constipation (great difficulty was experienced in overcoming this); and there were considerable rigidity and expression of pain on pressing the muscles. The knee-jerks were exaggerated. As regards mind, his attention could not be gained and he gave no indication of understanding, was unintelligible, and muttered unceasingly. He lay recumbent but was most restless and resistive. He could not control his emunctories. He was fed with great trouble. He was sleepless and appeared to be in pain. He got rapidly worse despite all treatment; he looked exceedingly ill and emaciated; the pulse became feeble; there was increasing dyspnœa (there were a few râles at the bases of the lungs); he was sleepless and in constant motion. Death occurred on March 6th (13 days after admission, about six weeks after the illness was first noted).

Necropsy.—A post-mortem examination was made 41 hours after death. The only positive indications of disease were as follows. The dura mater was rather adherent to the skull; the leptomeninges were congested and the cerebral cortex was markedly so. The brain substance was softened. The weight of the brain (probably with soft membranes and before opening, though not stated) was 54 ounces. The lower lobes of both lungs were congested and there was a small recent pleuritic patch at the base of the right lung. The liver, the spleen, and the kidneys were congested.

CASE 3.—The patient was a married man, aged 40 years. This was his first attack. He was admitted to the asylum on April 15th, 1905. The family history was as follows. One grandfather was "eccentric" and one of the patient's children died from tuberculous meningitis; nothing further abnormal could be ascertained. With regard to his personal history he drank too much at times—was "mad when in drink." The cause of the present attack (which was only of four days' duration) was great excitement during the religious revival. The following is a summary of the medical certificate of admission: "Religious mania with the usual symptoms, including refusal of food." He lived on milk-and-water for some time. On admission his temperature was subnormal (and it was not found above normal till the day of his death, when it was 100° F. in the morning). He was emaciated, pale, and greatly reduced physically. The knee-jerks were much exaggerated. The mouth was dry, the tongue was coated and tremulous, there were sordes on the teeth, and constipation was present. Mentally the patient was very agitated, restless, shouting, gesticulating, and incoherent. He continued thus, passing evacuations under him; he was fed by the tube; he was sleepless (no hypnotics were of any avail). Four days after admission he was removed to the infirmary ward owing to increasing exhaustion. He now took from the attendant four pints of milk and four eggs daily. His face was expressionless. The pulse was good. There was some dyspnœa with coarse râles at the base of the right lung. The temperature was normal. There was general muscular tremor. On the 22nd he was restless, with increasing dyspnœa. The respirations were 45, the pulse was more feeble and rapid, and the temperature was 100°. He died at noon on April 22nd (seven days after admission). For the last three or four days of life he showed no mental reaction but lay in bed taking no notice, expressionless, silent, giving no indication of understanding what was said.

Necropsy.—A post-mortem examination (for an unavoidable reason) was made 71 hours after death. The only positive indications of disease were thickening of the pia arachnoid which peeled easily in large sheets; the grey and white matter of the brain was soft on section. (These last two conditions no doubt were aggravated by length of time between death and the necropsy.) There was congestion of both lungs; the spleen was congested and friable. There was nothing further. The weight of the brain was 53 ounces (with soft membranes).

CASE 4.—The patient was a married man, aged 46 years. It was his first attack. He was admitted to the asylum on Jan. 25th, 1896. His family history was as follows. His father was intemperate and an aunt had a stroke of hemiplegia. The patient was the father of nine children, of whom five died in youth from no special disease; his wife had had two miscarriages also. With regard to his personal history he had had an attack of influenza three years before this illness but apparently made a good recovery. The present attack was of one week's duration; the supposed cause was domestic trouble. The following is a summary of the medical certificate of admission: "Violence, some ideas of exaltation, refusal of food, restlessness." On admission he was very restless and resistive, unintelligible, agitated, required feeding by the tube, stared before him, and appeared to have visual hallucinations. He was utterly confused. Physically he was well nourished; he had an ulcer on the lower third of the right leg, on the antero-internal aspect, and several small scars about the front of the right knee, also one scar on the left knee. There was nothing infiltration of the surrounding tissues lead to stiffening and induration. Under treatment this diminishes, hence the increase noted in the mobility of the uterus. The improvement following the use of Doyen's serum has been ascribed to a similar effect.

---

[1] See THE LANCET, August 16th, 1902, p. 440.

The pelvic glands.—In four cases (Nos. 1, 4, 5, and 8) no glands could be found, despite a thorough search for them. Dr. J. H. Willett, who assisted me, bears me out in this. In Case 7 the operation was abandoned and the glands were not sought for. In the remaining five cases iliac glands were found on both sides in three (Cases 2, 3, and 10) and on one side in one (Case 9). In Case 6 the obturator glands on both sides were enlarged.

Microscopical examination has resulted as follows:—Case 2: no disease found on either side. Case 3: Right iliac glands cancerous. Case 9: Left iliac glands cancerous. Case 10: left iliac glands cancerous. Case 6: right obturator glands cancerous. Out of ten cases the glands were found to be cancerous in four—i.e., 40 per cent. It should be stated that sections of these glands were not taken by the serial method—the only trustworthy one—but merely from parts of the glands which appeared suspicious. Possibly, therefore, further investigation of Case 2 might result in the finding of diseased areas. Wertheim estimated that the glands were diseased in 35 per cent. of cases and his figures have been confirmed by Döderlein, Zweifel, and Kleinhaus. Von Rosthorn puts his figures as high as 57·5 per cent., while those of an American observer (Wakefield) are only from 25 to 30 per cent. Wertheim states that of 35 cases in 100 two-thirds show cancer cells arranged in alveoli. In the remaining third there was no alveolar arrangement, but instead tube or bag-shaped formations, lined by high cylindrical epithelium, often possessing cilia. He was inclined to believe that these appearances were to be regarded as having a connexion with carcinoma of the cervix until Meyer of Berlin found similar changes in the pelvic glands of patients who had died from eclampsia or peritonitis. Since this Wertheim has found the same appearances in glands from a patient whose death was attributed to multiple pelvic abscesses. His figures therefore require considerable modification.

Of my own cases, the most striking instances are Cases 6 and 10. Both were typical examples of cases suitable for vaginal hysterectomy. The disease appeared to be limited entirely to the cervix and the mobility of the uterus was normal in each case. Yet in Case 6 the right obturator gland was cancerous and from Case 10 was removed the largest cancerous gland I have yet seen. In both these cases the performance of vaginal hysterectomy would have been futile so far as eradication of the disease was concerned. Improvement succeeding removal of the primary growth would speedily have vanished as the secondary untouched focus advanced. Extirpation of cancerous glands is no guarantee that all disease has been eliminated. Experience may show that the presence of infected glands should be a contra-indication to radical operations, but in the present state of knowledge a "radical" operation, to deserve its title, should include removal of all possible areas which are commonly diseased. In four other cases (Nos. 2, 3, 4, and 7) the local conditions were such that vaginal hysterectomy would unhesitatingly have been performed. In only one of these the glands were found involved by cancer, so that out of six cases in which vaginal hysterectomy would ordinarily have been selected as the operation of choice the pelvic glands were cancerous in three. There were four cases (Nos. 1, 5, 8, and 9) in which the vaginal operation could not possibly have sufficed. Its performance would probably have been attempted in Case 1, but in the other three the interference with uterine mobility was too great even to justify the attempt. In three of these cases no glands were to be found at the operation (Nos. 1, 5, and 8).

Ligature of the internal iliac arteries produced no after-effects at all beyond some temporary lividity of the skin area supplied by its branches. That it is not without its risks is shown by the case recorded by Cullen in which there occurred gangrene of the leg necessitating amputation. In the same case it was noted later that "it appeared as if all the pelvic organs were sloughing away." Ligature of the artery is invaluable in some cases, absolutely checking the oozing of blood which obscures the field of a difficult operation and which thereby increases both its duration and its risks. After the ligature has been tightened the veins seem to collapse entirely; they were never tied for the reason that they were never seen. The only cases in which hæmorrhage was severe were those two (Nos. 4 and 7) in which venous plexuses were wounded. The bleeding in Case 7 was alarmingly free but it was readily checked by pressure, as in a similar case related by Cullen.

Mortality.—Three deaths occurred out of ten cases, a rate of 30 per cent. It is scarcely necessary to recall the heavy mortality which led to the abandonment of Freund's operation—one of 76 per cent. Since 1895 this percentage has been steadily diminishing. Between 1900 and 1902 Wertheim operated on 31 cases with six deaths—18·2 per cent. Jonnesco's first series of ten cases had a mortality of 30 per cent.; his second series of 60 per cent.; and of the third series of ten cases every patient recovered. As he remarks, there seems to be a direct relation between the mortality on the one hand and experience in selecting cases and acquired operative skill on the other. This is perhaps, at present, the keynote of the matter. The operation, radical as it is and dangerous as it may be, requires that only selected cases be submitted to it—cases in which there is the possibility of removing the diseased uterus surrounded by a clear zone of sound, or apparently sound, tissues. Further desiderata are absence of much fat on the abdominal wall, a fairly roomy pelvis, and a good general condition of health. The anatomical position and relations of the mamma and of the uterus differ too much to render any comparison between them of great value but there is a striking similarity between the histories of the surgical progress in the treatment of the cancerous affections of each. First, removal of part, then of the entire organ; finally the organ *plus* its surrounding tissues, lymphatics, and glands. Extensive operations for cancer of the breast are practised now with but trifling mortality and are followed by more prolonged periods of subsequent immunity than were known in the past. Lessened mortality is largely due to modern asepsis but prolongation of immunity can only be due to freer excision. What has proved of value in the case of the cancerous mamma can at least be tried for the cancerous cervix uteri. Whilst routine removal by the vaginal operation ignores the possibility of outlying disease the results can only be disappointing. Is it not time to face the facts, to recognise that in every 100 cases submitted to vaginal hysterectomy diseased areas remain untouched in at least a fourth of the number? Surely the procedure is only palliative in these cases, and as such should be limited in its applications.

It is possible that the clearing up of the mystery surrounding the etiology and pathology of cancer may establish a rational basis for treatment. It is also possible that the abdominal operation may prove to be inadequate. In the meantime my inclination is to regard the combined radical operation as the one which seems to offer a reasonable chance of success, provided that its application be restricted to suitable cases.

Liverpool.

FIVE FATAL CASES OF ACUTE MENTAL DISORDER, PROBABLY ACUTE DELIRIUM.

By EDWIN GOODALL, M.D., B S. LOND.,
F.R.C.P. LOND.,
MEDICAL SUPERINTENDENT, JOINT COUNTIES ASYLUM, CARMARTHEN.

THE following cases appear to me to be worth recording on account of their rarity and severity, their rapid and lethal course, the obscurity of their pathogenesis, and, in three of them, the comparative insignificance of the naked-eye cerebral changes. As regards rarity, I find but five instances in a series of 451 necropsies, and undoubtedly the very great majority of such cases come to necropsy. Having regard to our ignorance of the nature of the disorder which these cases illustrate, I am of opinion that all such should be brought forward with a view to stimulate inquiry. The notes in these cases are not so full as could be wished, for reasons beyond my control; nevertheless, they serve to give a fairly good picture of the conditions observed. In the record of post-mortem appearances only positive (morbid) conditions are noted for reason of space.

CASE 1.—The patient was a married woman, aged 43 years. This was her first attack and she was admitted

A good deal of information has been collected during the last few years showing that when retinal changes are present an indication is given of the serious condition of the kidney disease and that life will only be, in the majority of cases, a question of months. Dr. Miles Miley, in a paper before the Ophthalmological Society in 1887, related particulars of an examination of in-patients he had conducted at the London Hospital. He was able to trace the duration of life in 45 cases and ascertained that death ensued in under one month in 13 cases; under two in seven cases; under three in six cases; under four in one case; under five in six cases; under six in four cases; under seven in one case; under eight in two cases; under nine in one case; under 11 in one case; under 14 in two cases; and under 18 in one case. One lived nearly 18 months and two 14 months, all the rest dying before the year was out. The average duration of life in these cases was four months.

At the same time that Dr. Miley's paper was read I contributed a short one to the discussion in which reference was made to eight cases. I shall allude to these instances when, later, I deal with those more particularly treated of in this article and they need not therefore be further mentioned at present. I remarked, however, on that occasion that there is a considerable difference in mortality statistics compiled from hospital as opposed to private patients and especially private ophthalmic patients. The former are inmates of the hospital on account of their kidney disease, whereas the ophthalmic surgeon's patients consult him owing to failure of sight, the discovery of the retinitis frequently leading to the detection of Bright's disease which had hitherto been unsuspected. It is to my mind clear, therefore, that in considering the prognostic value of albuminuric retinitis a sharp line must be drawn between hospital and private patients. Those in better social position have the means of taking the hygienic care requisite in Bright's disease and possibly alcoholism plays a more important part in the class met with in hospitals. It will be found that the period of life after the detection of retinitis is longer in private patients, short as it is, than in those set forth in Dr. Miley's cases. The statistics of Mdlle. Possaner are of interest in this connexion.[2] Out of 67,000 patients (45,000 observed at the clinic in 30 years, 22,000 private patients of Professor Haab) albuminuric retinitis was associated with chronic nephritis in 131 cases, or 1·9 per cent. After eliminating the doubtful cases Mdlle. Possaner inquired into the 131 cases mentioned above. Of 80 she was able to obtain certain information but eight had to be left out; for example, owing to accidental death. Of the remaining 72 cases she found the end different according to sex and social position; of 39 patients from the private *clientèle* 23 only, or 59 per cent., succumbed in two years following the diagnosis, the women presenting a mortality of 58 per cent. and the men 61·5 per cent. Five men and five women were alive after a period varying from two and a quarter to six years for the men and three and a half to 11 years for the women. Out of 33 hospital patients all the men died in less than two years and also 68·4 per cent. of the women. Four women were still alive, of whom one was examined six years before. These differences following sex and social position appear to indicate that the want of hygienic care and alcoholism play an important part in the curability of chronic nephritis. The age of the patients varied from six to 70 years, the great majority having passed 40 years. Two only were syphilitic; they survived, one three months and the other two and a quarter years. The author concludes that the prognosis as to life is very serious but not so much so as is generally believed, even in the chronic forms of renal affections and there is hope, she contends, of ameliorating the sufferings as well as prolonging the life of the patient. It must be noted that no mention is made in the abstract from which I quote whether or not Mdlle. Possaner includes the nephritis of pregnancy in her cases.

Dr. E. O. Belt of Washington has collected and tabulated from the literature of the subject and his own practice and that of other surgeons 419 cases in which the continuance of life after the recognition of the retinal lesions had been noted. Of cases in private practice 62 per cent. died in the first year and 14 per cent. lived more than two years. Of cases in hospital practice 85 per cent. died in the first year and only 6 per cent. lived more than two years. Of all cases 65 per cent. died in the first year and 6 per cent. lived more than two years. One patient had survived 17 years but several surgeons of larger experience had seen none who survived more than two years. The better prognosis in private cases is to be ascribed to superior hygienic surroundings.[3] Dr. C. S. Bull, before the American Ophthalmological Society in 1886, presented an analysis of 100 cases of retinitis occurring in the course of Bright's disease. He regarded the prognosis of life as very unfavourable. Out of the exact total of 103 cases collected during 13 years 86 had died, 57 during the first year and 12 during the second year; of the 17 still living 14 were seen during the last six months and one had been seen seven years previously. Dr. Gruening stated also that he had found in 100 collected cases that none had lived over two years after the diagnosis of albuminuric retinitis had been made.

In my previous paper to which reference has been made eight cases were mentioned. The ages of these were 37, 34, 56, 59, 31, 66, 23, and 39 years. Five were males and three were females and the period elapsing from the time when first the retinal disease was recognised to death was as follows: 6 weeks, 4½ months, 5½ months, 10 months, 2½ months, 5½ months, 2 months, and 14 months. These were all private cases except one.

With a view to ascertain how far my experience

Table of Cases of Albuminuric Retinitis in Bright's Disease.

No.	Sex.	Age.	Date when first seen.	Date of death when ascertained.
1*	M.	37	Nov. 29th, 1887.	Jan. 12th, 1888.
2*	M.	34	August 19th, 1887.	Jan. 2nd, 1888.
3*	M.	56	Jan. 8th, 1884.	June 27th, 1884.
4*	M.	59	May 7th, 1883.	April, 1884.
5*	F.	31	Nov. 22nd, 1881.	Feb. 3rd, 1882.
6*	F.	66	Oct. 28th, 1886.	March, 1887.
7*	F.	23	—	Six to eight weeks after diagnosis.
8*	M.	39	August 31st, 1875.	Jan. 7th, 1877.
9	M.	60	July 18th, 1899.	Oct. 13th, 1901.
10	M.	57	July 23rd, 1900.	July 11th, 1902.
11	F.	35	March 10th, 1891.	Living.
12	M.	36	July 13th, 1903.	,,
13	M.	24	Dec. 31st, 1887.	Could not ascertain it.
14	M.	48	Nov. 9th, 1897.	March 21st, 1898.
15	M.	45	Feb. 15th, 1893.	January, 1900.
16	F.	54	July 11th, 1894.	Could not be ascertained.
17	M.	55	Sept. 3rd, 1892.	April 17th, 1895.
18	F.	45	Jan. 7th, 1897.	Living.
19	M.	50	June 2nd, 1897.	March 15th, 1898.
20	M.	33	Feb. 3rd, 1890.	March 10th, 1890.
21	M.	36	Nov. 11th, 1889.	January or February, 1890.
22	M.	51	Oct. 17th, 1892.	Nov. 26th, 1892.
23	F.	58	Dec. 22nd, 1890.	April 13th, 1891.
24	F.	39	March 15th, 1895.	August 28th, 1895.
25	M.	57	July 7th, 1894.	Oct. 24th, 1894.
26	M.	47	July 13th, 1893.	Sept. 18th, 1893.
27	F.	39	March 30th, 1893.	Dec. 9th, 1893.
28	M.	42	Feb. 19th, 1898.	January, 1899.
29	M.	50	March 30th, 1904.	Sept. 7th, 1904.
30	F.	30	Feb. 14th, 1900.	Dec. 14th, 1901.
31	F.	35	June 12th, 1901.	Jan. 4th, 1904.
32	M.	54	July 22nd, 1903.	October, 1904.
33	M.	38	Oct. 26th, 1894.	April, 1899.
34	F.	41	Sept. 22nd, 1896.	Could not be traced.
35	F.	42	Feb. 9th, 1899.	,,
36	F.	32	Nov. 11th, 1902.	,,
37	F.	20	June 7th, 1897.	,,
38	F.	44	July 24th, 1894.	,,
39	M.	54	Oct. 15th, 1894.	,,
40	F.	69	Nov. 10th, 1892.	,,

* These are the 8 cases recorded in my previous paper.

[2] On the Duration of Life after the Appearance of Albuminuric Retinitis, Annales d'Oculistique, 1894, p. 362.

[3] American Medical Association, 1895, Ophthalmic Section, abstracted in Ophthalmic Review, 1896, p. 58.

else noteworthy except that the tongue was dry and furred. Subsequent entries note especially extreme restlessness—"rolling about the floor"; the patient was only partially conscious. He was fed by the tube and the urine was drawn off. There were sordes on the lips and teeth. He got gradually feebler. On Feb. 3rd the pulse was 90, scarcely perceptible, the temperature was 98° F., the face and lips were dusky, and respiration was rapid. There was low muttering delirium. Death took place on Feb. 4th, ten days after admission.

Necropsy.—A post-mortem examination was held on Feb. 6th at noon. The skull cap was deeply injected and the dura mater was strongly adherent to either side of the middle line. The pia-arachnoid stripped normally, there were no erosions of the cortex, and the gyri were well arranged and of good size. All parts of the brain, including the grey and white matter, were extremely congested. There was no excess of cerebro-spinal fluid. Both lungs were congested. The brain weighed 58 ounces (probably with soft membranes). Nothing else was noteworthy. There was no evidence of syphilis in the testicles or elsewhere. This case during life was regarded as possibly one of dementia paralytica but there was nothing in the post-mortem appearances to indicate this disease.

CASE 5.—The patient was a married man, aged 51 years, a hosier. It was his first attack. He was admitted to the *asylum on May 13th, 1905. His family history was free* from disease of any importance. With regard to his personal history, he had had influenza "this year and many times." The cause of his present illness was believed to be religious ("revival") excitement; its duration was 14 days prior to admission. The following is a summary of the medical certificate of admission: "Religious mania, sleeplessness, restlessness." On admission the patient looked at least ten years older than he was; he was feeble and greatly emaciated. No cardiac murmur was heard; his pulse was feeble (120). The tongue was coated. He was very restless and resistive and was in a dazed condition. He refused food and was fed by the tube. He was quite incoherent. He passed evacuations beneath him. He remained in this condition until death occurred at 2.15 A.M. on the 17th (four days after admission). On the 16th the morning temperature was 99·4° and the evening temperature was 100°.

Necropsy.—A post-mortem examination was held on the 18th at 1.45 P.M. Permission was given to examine the head only. Nothing abnormal was noted excepting that the pia arachnoid peeled in large sheets (not opaque), the brain tissue was soft and œdematous, and the grey matter was but little congested. The weight of the brain with soft membranes was 55 ounces. This case resembled the others clinically. The necropsy was not, however, complete, as in the previous cases.

The above cases are, I think, best placed under the heading of "acute delirium" or "acute delirious mania." In three of them the marked congestion of the meninges and cerebrum and marked softening of the latter which are recorded in descriptions of acute delirium were not present. The brain-weights were, however, increased in all, pointing to œdema. The chief clinical features of these cases are, I think, the profound disturbance of consciousness, the restlessness (a constant movement, with resistance and without violence, the patient being recumbent), and the adynamic condition. This last rapidly increases and, in my experience, treatment is commonly of no avail. I believe that subcutaneous injections of sterilised salt solution should be tried more freely in these conditions, with the object of diluting and eliminating toxin. Hitherto I have not injected more than 500 cubic centimetres subcutaneously at a time, using Hayem's solution (seven grammes of common salt to one litre of water) every other day, sometimes daily, this being the method described by Jacquin,[2] whose article first drew my attention to this treatment. Dr. Mosher of the Albany Hospital, New York,[3] injects as much as 1700 cubic centimetres twice daily. Some prefer to introduce the solution into the bowel. I am not aware that there is sufficient experience to decide which method, if either, gives the better result. The first named is certainly the more troublesome, involving disinfection of apparatus.

In two of the above cases the mental illness was dated back by the friends to an attack of influenza and in two others there was intense religious excitement, both of which are causes of acute delirium recognised by authors. The description given by the best English and foreign text-books of the condition above portrayed sufficiently demonstrates our lack of knowledge of its pathogenesis. Such descriptions commonly refer to the probability or certainty of toxæmia in acute delirium, even where the disease occurs independently of a specific malady, such as typhoid fever or pneumonia, but little or no information is forthcoming as to the nature of the toxin and as to its source beyond the statement that the latter may be exogenous or endogenous. As far as I am aware there is no record of the discovery of a specific organism in acute delirium apart from the observations of the Italian observers, Bianchi and Piccinino, who found a bacillus in the blood, an observation which is in need of ample confirmation. Cases of auto-intoxication with mental disturbance in diseases of the kidneys, the liver, the heart (cyanosis), and other organs have been described[4] and the gastro-intestinal tract is commonly regarded and perhaps somewhat too familiarly referred to as a source of endogenous toxins, on which theory the stomach has been washed out and the intestines have been freely treated with such drugs as naphthalene with a view to disinfection, in the feasibility of which, as regards the bowel, I disbelieve. There is another form of auto-intoxication to which Mott has called attention[5] and which consists in poisoning by the products of metabolism of nerve substance, such as choline. *Choline, it appears from the source referred to, does not* normally exist in the blood in sufficient quantities to be recognisable but can be detected in the blood "practically in any degenerative process affecting the nervous system if extensive enough." Its escape into the blood in large quantities and its accumulation therein may cause auto-intoxication. As, however, choline is not a powerful toxic substance (Mott found it in abundance in a case of disseminated sclerosis, which is certainly not a type of acute toxic disease) it would appear improbable that this substance could produce such a rapid and fatal disease as acute delirium. But other products of the decomposition of the proteid matter of the nervous system may be more active poisons.

In diseases caused by exogenous toxins, such as the infectious fevers, there is as a rule a decided rise of temperature, whereas in cases of acute delirium the temperature is often but slightly raised, sometimes not at all. This point, together with the consideration that the latter disease is sometimes referable to a psychical cause with attendant physical reduction, would rather indicate that it is of the nature of an auto-intoxication. I consider that such cases as the above constitute one of many arguments for the establishment of a psychiatric department in connexion with our great teaching hospitals. For the conditions necessary for research in the more obscure fields of psychological medicine, which conditions include proper facilities for animal experimentation and for collaboration with workers in allied departments of medical science, are not to be found, and in my belief will never be established, in county asylums in this country.

THE DURATION OF LIFE AFTER THE APPEARANCE OF ALBUMINURIC RETINITIS.

BY SIMEON SNELL, F.R.C.S. EDIN.,
OPHTHALMIC SURGEON, ROYAL INFIRMARY, SHEFFIELD; PROFESSOR OF OPHTHALMOLOGY, UNIVERSITY OF SHEFFIELD.

THE prognostic significance of albuminuric retinitis may well be regarded as a subject of considerable importance. Retinitis occurs in about 30 per cent. of all cases of Bright's disease. "This percentage is subjected to very slight variation by different observers. For instance, Norris stated that 25 per cent. of cases of nephritis were attended by retinal changes; Eales demonstrated by his statistics that its frequency was 28 per cent.; while Galezowski places it at 33 per cent. It seems to be more frequent in males than in females."[1]

---

[1] Albuminuric Retinitis, by L. Webster Fox, A.M., M.D. New York Medical Journal, June 25th, 1904.

The abdominal wound was then closed except at its lower end, where a large drainage-tube was inserted running down to the bladder. A No. 7 English catheter was tied into the bladder.

The chief points in the subsequent history of the case were as follows. The tube was removed on the fourth day. The wound healed by first intention and the stitches were removed on the tenth day. On the second day there was some vomiting but this soon passed off. On the third day the bowels acted freely, nourishment was well taken, the pulse improved and the temperature remained normal. The bladder was washed out daily with boric acid lotion and the catheter was cleansed and replaced. There was some hæmaturia with a few clots on the first day, but the urine soon passed clear. On the seventh day the catheter was removed. Urine was passed normally from this date. There was rectal incontinence at first, which rendered the nursing very difficult; this passed off after a week. During the first 48 hours there were much pain and restlessness. On the third day the latter became extreme, the patient developed hallucinations of sight and hearing, saw dead bodies all round him and imagined that the attendants were going to murder him. The necessary rest was only obtained by repeated injections of morphine. After about a week he became quieter and on the twenty-first day he was allowed up. There has been no further local trouble. The patient now wears a double inguinal truss, the right pad of which was made specially large and fitted with a depression in its lower part to prevent injurious pressure on the bladder.

Hernia of the bladder is sufficiently uncommon to be of special interest and I am encouraged to publish the case by the kind permission and help of Dr. Robert Jones, medical superintendent. In this case the greater portion of the protruded viscus was extraperitoneal and, taking into consideration how much more adherent it was than the intestinal hernia, was probably of longer duration than the latter. On the other hand, the dragging of a hernial sac on the parietal peritoneum is far more likely to cause a hernia of the bladder. The fact that on passing the finger into the abdomen through the hernial sac the peritoneum was felt to be clear on all sides, correctly interpreted, should have helped towards the true diagnosis, which would have been rendered certain by passing a catheter during the operation.

The peculiar solid, elastic feel of the protruding portion of the wall of the bladder in no sense suggested a hollow viscus; and I am not aware of any text-book description of hernia of the bladder which points out this feature. Yet in reconsidering the case in the light of experience the folded and perhaps hypertrophied muscular coat may, in the absence of distension by urine, be expected to give rise to this sensation of firmness and solidity.

Claybury.

TWO CASES OF ACTINOMYCOSIS.

BY DOUGLAS DOUGLAS-CRAWFORD, M.B. EDIN., F.R.C.S. ENG.,

HONORARY SURGEON TO THE LIVERPOOL STANLEY HOSPITAL AND LECTURER UPON SURGICAL AND APPLIED ANATOMY IN THE UNIVERSITY OF LIVERPOOL.

IN THE LANCET of Oct. 29th, 1904, p. 1204, five cases of actinomycosis are recorded. During the past year I have had two cases under my care, each of which presents some points of interest.

CASE 1.—The patient was a ship's surgeon, aged 29 years, who bruised his left flank against a stanchion on the homeward voyage from the Amazon on Nov. 28th, 1903. Within a fortnight two small papules appeared over the bruised area but remained stationary for some time. These papules were associated with what the patient regarded as a cellulitis and the pain was so severe that he commenced hypodermic injections of morphine, gradually increasing the dose until he was taking eight grains per diem. Three months later—in February, 1904—the lesion began to spread rapidly until it reached the crest of the ilium, then again remained quiescent, but just before he came under my care it had extended over the buttock, inwards towards the crest of the os pubis, and upwards over the lower ribs. The patient was admitted to the Stanley Hospital on July 15th, 1904. He was very emaciated and tremulous—probably due to the morphine habit—and his urine contained a trace of albumin. The area of skin affected is somewhat indistinctly shown in the illustration but in addition to this there were two or three independently affected areas on the left thigh. The skin over the site of the lesion was purplish in colour, indurated in some parts and œdematous in others. Small sinuses were scattered over the affected area, and here and there were seen pustular elevations, any one of which upon pressure discharged a greyish-coloured pus and left a narrow superficially burrowing sinus. The pus was examined microscopically and although the presence of the ray fungus was not perhaps absolutely proved yet I decided to excise the whole of the infected area, for I felt I had ample grounds for excluding the other two diseases which give rise to somewhat similar chronic ulcerations—viz., tubercle and syphilis. The lesion was limited entirely to the skin except at one spot just over the external abdominal ring and here the aponeurosis of the external oblique was evidently diseased. The extensive raw surface was somewhat narrowed by a plastic operation but a considerable area was left to granulate. The patient suffered severely from shock the same evening but after that made rapid progress; we had, however, some difficulty with portions of the scar tissue which time after time became hæmorrhagic and broke down, leaving a weak ulcer. However, after energetic scraping we finally obtained a sound healthy scar five months after operation. Microphotographs kindly taken for me by Dr. R. E. Kelly showed the fungus in two forms—one simply the mycelium imbedded in a hyaline material and the other a radial arrangement with hyaline clubs at the periphery.

To show the extent of skin affected in Case 1.

CASE 2.—This patient was sent to me by Dr. T. F. Williams of Cefnybedd. The patient gave the following history. Six weeks previously a painful lump appeared beneath the right half of the mandible just after an attack of quinsy. This was attributed to a carious molar but its extraction had no effect upon the pain and the swelling rather appeared to increase. Upon examination the swelling was found to extend from the angle of the jaw on the right side across the middle line in front and beyond the level of the hyoid bone below; the skin over it was purple and œdematous and dotted all over with narrow sinuses and upon pressing one of them a creamy pus was discharged containing a very considerable number of small granules. The diagnosis was fairly obvious and was confirmed by examination of a "crushed granule" under the microscope. The patient had difficulty in opening his mouth, the jaw was not thickened, and the site of the extracted tooth appeared healthy. I operated on Oct. 1st, 1904. The operation consisted in excising the whole of the œdematous mass and meant the removal of the submaxillary gland, the digastric (anterior belly) and mylohyoid muscles and the lower third of the internal pterygoid muscle. The mandible was thoroughly exposed and found to be healthy. The point of entrance of the fungus must have been through the mucous membrane accorded with that of other observers I have collected all the instances in my private case-books subsequently to the date of publication of my first paper. I find records of 35 cases. Three of these must be at once excluded as the retinal affection was not typical. One of these died, however, about a couple of years later, one is living after three years, and the other cannot be traced. Of the remaining 32 suitable for our purpose I am unable to trace nine, thus leaving 23 (see table). Three are known to be living. Of these, one a man, aged 36 years, was first seen in July, 1904; the kidney affection had been previously recognised. Two were women and both had suffered during pregnancy. One, aged 35 years, seen in March, 1891, recovered vision partially, but became affected again in the next pregnancy, two years later, with resulting blindness. The other woman, aged 45 years, seen after the birth of the first child, in January, 1897, made a good recovery. These, with other instances of the albuminuria of pregnancy, will be considered again later. The remaining 20 were ascertained to have died as follows: two at the end of one month, two at two months, one after three months, two after four months, one after five months, one after six months, two after nine months, one after 12 months, one after 15 months, one after 22 months, two after 24 months, one after 28 months, two after 32 months, and one after four and a half years. The average duration of life in these cases is 14½ months, but added to the eight previously recorded, making a total of 28, the average is barely one year. This average (12 months), compared with Dr. Miley's of four and a half months for hospital patients, fully bears out the contention of the less fatal significance of renal retinitis in private patients. The period is, nevertheless, a very brief one and my cases, as well as the observations of others to which allusion has been made, clearly show that the appearance of changes in the retina is a sign-post of the systemic havoc wrought by the chronic nephritis and that it portends a fatal termination, it may be in a few months, and rarely longer than two years. The renal disease associated with pregnancy is rightly excluded from consideration in this connexion. For, fortunately, it not infrequently happens that with the termination of gestation the albumin disappears and the retinal disease clears up, though often vision may remain seriously affected and it is recognised that the condition is not fatal to life in the same way as in chronic Bright's disease. Among my cases is one instance (No. 31) of a woman who was affected during pregnancy. The renal condition, however, persisted, and it did not appear to me to fall precisely among ordinary cases of Bright's disease with pregnancy and it has not therefore been excluded.

Sheffield.

ON THE CHEMICAL MECHANISM OF GASTRIC SECRETION.[1]

By J. S. EDKINS, M.A., M.B. Cantab.,
LECTURER ON PHYSIOLOGY IN THE MEDICAL SCHOOL OF ST. BARTHOLOMEW'S HOSPITAL, LONDON.

It has long been known that the introduction of certain substances into the stomach provokes a secretion of gastric juice. This is regarded as in no sense depending upon mere mechanical stimulation of the mucous membrane and it has been thought that the nervous mechanism of the gastric glands may be susceptible to certain local chemical stimuli. On the analogy of what has been held to be the mechanism at work in the secretion of pancreatic juice by Bayliss and Starling it is probable that, in the process of absorption of digested food in the stomach, a substance may be separated from the cells of the mucous membrane which, passing into the blood or lymph, later stimulates the secretory cells of the stomach to functional activity. The following observations support this view. If an extract in 5 per cent. dextrin of the fundus mucous membrane be injected into the jugular vein there is no evidence of secretion of gastric juice. If the extract be made with the pyloric mucous membrane there is evidence of a small quantity of secretion. With dextrin by itself there is no secretion. Extracts of fundus mucous membrane in dextrose or maltose give no secretion; extracts of pyloric mucous membrane give marked secretion; dextrose or maltose alone brings about no secretion. If extracts be made with commercial peptone it is found that no secretion occurs with the fundus mucous membrane, a marked secretion with the pyloric mucous membrane; the peptone alone gives a slight secretion. If the extracts be made by boiling the mucous membrane in the different media the effect is just the same—that is to say, the active principle, which may be called "gastric secretin," is not destroyed by boiling.

Finally, it may be pointed out that such absorption as occurs in the stomach apparently takes place in the pyloric end. With the pig's stomach, in which the true cardiac region differs from the typical fundus region in having only simple glands as in the pyloric, extracts of the cardiac region in general have the same efficacy in promoting secretion as do pyloric.

St. Bartholomew's Hospital.

A CASE OF STRANGULATED HERNIA OF THE SMALL INTESTINE AND BLADDER.

By G. F. BARHAM, M.B., B.C. Cantab., M.R.C.S. Eng.,
ASSISTANT MEDICAL OFFICER, CLAYBURY ASYLUM.

The patient, a male, aged 70 years, was admitted into Claybury Asylum on March 5th, 1904, suffering from senile melancholia. He was restless, apprehensive, and had delusions of persecution and was impulsive at times. There was well-marked arterio-sclerosis with some cardiac hypertrophy. The lungs were healthy. The patient had a double inguinal hernia, on the right side direct and irreducible, on the left oblique and reducible. He was wearing an old double inguinal truss.

On March 9th he was visited at 9 A.M. He had vomited once early in the morning and was complaining of abdominal pain. He was lying on his back with the legs drawn up and was in evident distress. There was frequent retching; his pulse was 90, small and hard; his temperature was 98° F. There had been no action of the bowels for 24 hours and he had passed no urine during the night. There was a hard, tender swelling of the size of an orange, just above and to the right of the symphysis pubis; this was dull on percussion and conveyed no impulse on coughing. There were no other signs and the left hernia was easily reducible. The case was clearly one of strangulated hernia. A catheter was passed and about ten ounces of urine were withdrawn. At 11 A.M. chloroform anæsthesia was induced. With the usual antiseptic precautions the skin was incised over the swelling in a vertical direction, and after dividing and reflecting the various layers a hernial sac was exposed. The neck of the sac was then defined. It was easily separated from its surroundings except on its lower aspect where it was closely adherent to an ill-defined swelling, which, together with it, was protruding through a small opening in the abdominal wall. The sac was next opened and found to contain some blood-stained fluid, a small clot, and a knuckle of small intestine. After enlarging the ring the bowel could be drawn down and being in a healthy condition was returned into the abdomen. The sac was then held up out of the way with artery clips. As above stated, the sac was attached below to a swelling which was of about the size of a testicle, firm to the touch, and intimately adherent to its surroundings; it was covered by muscular and old inflammatory tissue and could not be defined at all clearly. On passing the finger into the abdomen through the hernial sac the peritoneum was found clear on all sides; the swelling could be felt passing through the ring but was not traceable beyond. In attempting to define this structure with the knife handle what appeared to be a hernial sac containing a little fluid was exposed; this was nicked and the opening was enlarged, when a small quantity of urine escaped. Through this opening a finger could be passed through the abdominal ring into the bladder. Every effort was made to keep the two parts of the wound separate. The hernial sac was dissected from the bladder as far as possible, ligatured, and the distal portion was excised. The bladder was closed by a continuous catgut suture passing through the outer coats and the whole wound was cleansed thoroughly with a 1 in 20 carbolic lotion, subsequently with boric acid lotion.

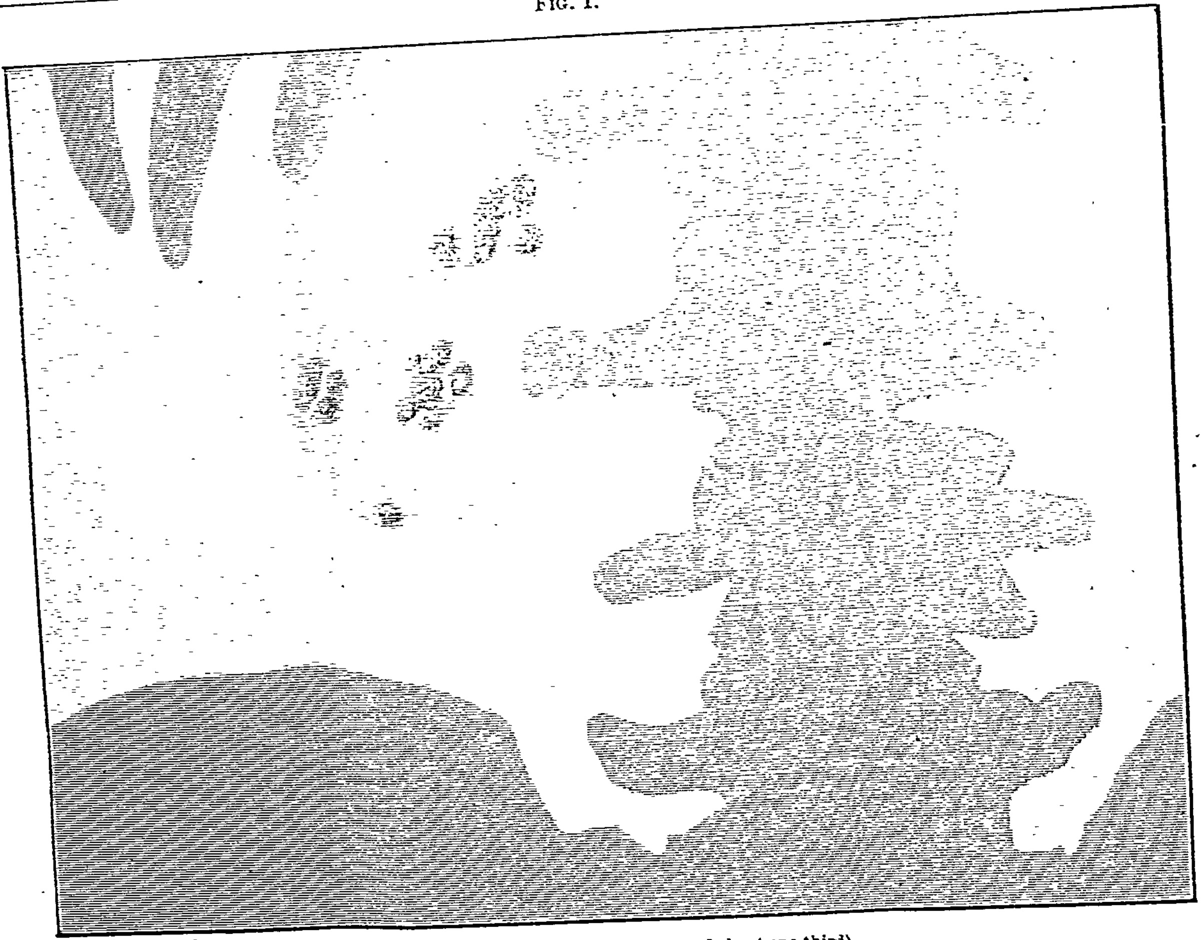
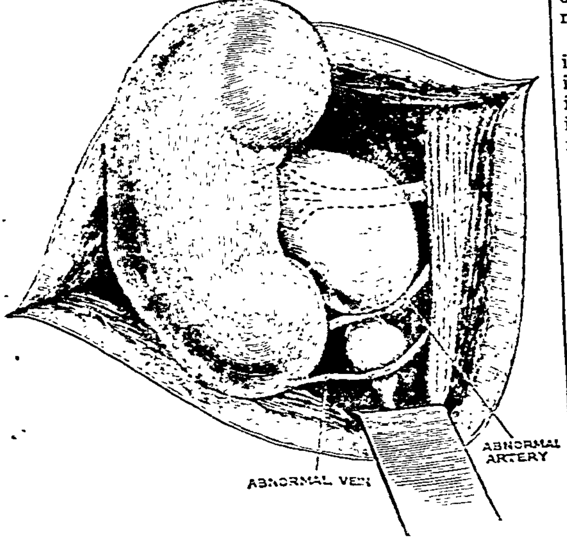
FIG. 1.



Appearances seen in radiography (reduced about one-third).

abnormal artery and vein passing to and from the lower pole of the kidney (see Fig. 2). The constricting artery was double ligatured and cut and the vein was treated in a like manner. The kidney was incised along its outer border. It was explored with the finger inserted into the incision, and 16 small calculi were separately removed. (The number and shape of these calculi corresponded with the shadows shown in the skiagrams.) The wound in the kidney was then closed by five sutures of silk and the small incision in the pelvis was sutured. The kidney was replaced within the abdomen and the wound was closed. The urine for four days contained more blood than is usual after such an operation, but in other respects the recovery was normal. The stitches were removed from the wound on the tenth day.

FIG. 2.



Showing abnormal vascular supply.

Note.—The bulging below the vein, as shown in the diagram, is incorrect.

Remarks.—The above case is one of very considerable interest from many points of view. It is of special interest in that it illustrates in a remarkable manner the increasing accuracy and exactness of the evidence which is now being furnished by radiography in cases of suspected renal calculus—evidence which with the improvement in the manufacture of tubes and the sensitiveness of the plates has in many cases rendered diagnosis a certainty. It is of pathological interest in that it shows how an abnormal vascular supply may interfere with the functions of the kidney; and it is of interest clinically in raising the question in what way and to what extent the earlier symptomatic history may be explained by the anatomical variation found at the operation.

THE CARDIFF INFIRMARY.—The sixty-eighth annual report of the Cardiff Infirmary has just been published. An interesting account is given of the growth of the institution since 1837, when there were 42 in-patients and 1074 out-patients. The income at that time was £617 and the expenditure £759. In 1904 2144 in-patients were admitted and 19,525 out-patients treated. The income amounted to £11,476 and the expenditure to £13,130. During the last ten years the annual income of the infirmary has only once exceeded the annual expenditure, and that was in 1903.

to the inner side of the angle of the jaw, its further path being along the internal pterygoid into the submaxillary triangle. The patient made a good recovery, the wound being perfectly healed when I saw him on Dec. 5th, two months after the operation, and all he suffered from was a slight facial paralysis due to division of some of the cervico-facial branches at the time of the operation. Microphotographs were taken from sections but in none did we find the typical radial arrangement with hyaline bodies, as shown in one of the photographs from the first case.

With regard to treatment, in both cases I excised the whole area affected, considering it more satisfactory than scraping, and in the second case it would hardly have been possible to remove the whole of the disease with the curette. Operation was undertaken so soon after seeing both patients that one cannot say much as to the value of iodide of potassium. The first case had none but in the second I continued the administration of 60 grains every 24 hours for a period of six weeks and in addition irrigated the wound with a solution of iodine during the first week and later injected iodopin into two or three suspicious-looking spots in the deeper parts of the wound and packed the cavity with gauze soaked in iodopin. I think the patient derived some benefit from this method of dressing and he was able to leave the nursing home in three weeks with a healthy granulating surface.

As to the mode of infection the first case presents some difficulty. A few cattle were carried on board ship for the use of the crew and part of the duties of the patient's steward was to feed them. It is possible that the infection may have been conveyed through the handling of my patient's clothes. The small isolated spots, I feel convinced, were produced by the patient himself through the medium of his hypodermic syringe. The second case is fairly simple. The patient is a butcher; often keeps his cattle for a few days before slaughtering them and superintends the feeding himself.

There is a marked difference in the rate of growth in these two cases, the first being fortunately extremely chronic, and it is of interest to note that in this case were seen the hyaline bodies which are not usually found in human actinomycosis. Attempts were made both by Dr. Kelly and myself to obtain cultivations, but they were unsuccessful, as were also some inoculation experiments upon guinea-pigs.

P.S.—I have seen both patients within the last few weeks; both remain perfectly well, but my first patient complains of anæsthesia of the skin over the crest of the ilium and just over the region of the os pubis.

Liverpool.

NATIONAL SOCIETY FOR EMPLOYMENT OF EPILEPTICS, THE COLONY, CHALFONT ST. PETER.—The twelfth annual meeting of the governors of this society was held on July 10th at the London offices, Denison House, Westminster. The chair was taken by Mr. E. Montefiore Micholls and the reports of the honorary medical staff and the executive committee for the year 1904 were received and adopted. From the former report it appears that the general health of the colonists during the year was very good. There was entire freedom from any epidemic or contagious disease and only two colonists died during the year. Medicinal remedies, it is pointed out, form only one item in the treatment of this malady, the most complete treatment being that which is carried out in such institutions as the Chalfont Colony, "where the epileptic is guided along hygienic lines in respect of the suitable quantity and quality of food, the proper allotment of work and rest, and the carrying out of those physical exercises consistent with the malady." The report of the executive committee shows the past year to have been one of great progress and extension, a new home for the special benefit of Hampshire cases having been opened during the year, and also an administrative house and various other buildings. Notwithstanding these additions, however, the accommodation is stated to be still entirely insufficient to meet the demand for admission, especially as regards the women's department, where the congestion of applications is so great that unless additional accommodation is provided each applicant will have to wait several years before her turn for admission will come, the malady in the meantime becoming hopelessly confirmed, so that the remedial aims of the colony would to a great extent be defeated. Funds for extension are therefore urgently needed.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum propriae collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

THE MIDDLESEX HOSPITAL.

A CASE OF HYDRONEPHROSIS AND RENAL CALCULI, IN WHICH 16 SMALL CALCULI WERE DETECTED BY THE X RAYS AND IN WHICH THE HYDRONEPHROSIS WAS DUE TO CONSTRICTION OF THE PELVIS OF THE KIDNEY BY AN ARTERY AND A VEIN PASSING TO ITS LOWER POLE.

(Under the care of Mr. HENRY MORRIS.)

FOR the notes of the case we are indebted to Dr. W. Sidney Sweet, house surgeon.

The patient, a married woman, aged 29 years, suffered from pain in the abdomen, nausea, and occasional vomiting for nearly ten years. At first she ascribed these symptoms to indigestion; as a girl she was anæmic. About four years ago she sought relief for pain in the left side (loin) and vomiting and was sent to a London hospital. There she was under the care of a surgeon who operated upon her and fixed the left kidney. After the operation her symptoms improved for about a year. She married and had two children, the last being born three months before admission to the hospital. A month after the birth of the last child she had a severe attack of pain in the left side extending down into the lower limb on that side. Subsequently she had other attacks which lasted from two to three hours and of such severity that she had to go to bed. She also had complained of a smarting sensation after micturition and some difficulty in starting and controlling the act. There was also a history of frequency of micturition both nocturnal and diurnal at times. On May 1st she was admitted to the Middlesex Hospital with the above symptoms. The urine was alkaline, with specific gravity varying from 1012 to 1020; there was a slight amount of albumin and a small quantity of pus, but no blood. On the 8th the urine contained a large quantity of pus. The patient was examined under chloroform and the bladder was sounded with negative result. The generative organs were found to be quite normal. The urine was examined for tubercle bacilli but none were found.

On May 16th the patient was transferred to the care of Mr. Henry Morris. She was then pale and thin and complained of pain in the left side. Her pulse was weak but regular and not unduly frequent; her temperature was normal. The urine was as described above. She was passing on the average 34 ounces in the 24 hours and there were five grains of urea to the ounce. She was radiographed and the skiagram showed a number of small but definite shadows arranged in groups of five, four, six, and one respectively—16 in all—and measuring on an average three millimetres in diameter. Each was quite regular and rounded (see Fig. 1).

On May 19th Mr. Morris operated. An incision was made through the old scar in the left loin and some strong fibrous bands were divided which were found connecting the kidney with the lumbar parietes the result of the previous operation of nephropexy. On exposing the kidney it was found to be small and its pelvis to be dilated considerably. A small incision was made in the pelvis and a ureteral bougie was passed easily along the ureter into the bladder. Less than half-way up the dilated renal pelvis a branch of the renal artery of considerable size crossed it obliquely on its posterior aspect. Parallel to the artery, and about half an inch lower down, was a branch of the renal vein. These vessels were running to and from the lower pole of the kidney respectively. The artery was found to be lying in a groove on the wall of the pelvis of the kidney. Above it the pelvis was dilated. There could be no question but that here was a hydronephrosis resulting from obstruction in the pelvis of the kidney as the result of a constriction caused by an connexion with the orbital cyst. From a clinical point of view the diagnosis was by no means easy, and the differentiation from meningocele was a matter of considerable uncertainty and anxiety. The pathological interest centred in the very free communication that existed between the interior and exterior of the globe by a wide coloboma at the posterior pole, a condition which permitted the free passage of the fluid secreted by the well-developed ciliary processes into the cyst, producing the increase in size which necessitated operation.

The following case and card specimen were shown:—

Mr. SECKER WALKER: Diagrammatic Model showing the path of light rays in various forms of astigmatism.

Mr. ORMOND: Keratomalacia.

OBSTETRICAL SOCIETY OF LONDON.

Endothelioma of the Uterus.—Malignant Embryoma of the Ovary.—Extra-uterine Gestation.—Large Fibrotic Uterus with Calcification of the Arteries.—Small Intestine Adherent to the Stump of an Ovarian Tumour.

A MEETING of this society was held on July 5th, Dr. W. R. DAKIN, the President, being in the chair.

Mrs. SCHARLIEB, M.D., described a case of Endothelioma of the Uterus in a woman, aged 50 years, who for 11 years had noticed an abdominal tumour, associated with hæmorrhage and bladder symptoms, and thought to be a fibroid. It grew rapidly and at the time of operation reached two and a half inches above the umbilicus. It was removed, together with the uterus and appendages. The patient made an uneventful recovery and remains perfectly well now, more than two and a half years afterwards. The tumour weighed 44 ounces. The uterine cavity was enlarged and measured three and a quarter inches in length, the mass bulging into it from the upper part. The mass rose up from the fundus in the form of a cyst of the size of a six months' pregnancy. The cyst contained spontaneously coagulating slightly yellow fluid. The wall of the main cyst contained other cysts, varying in size from that of a cherry to that of a hen's egg. They were filled with clear fluid; their walls were perfectly smooth and lined by a definite membrane, visible to the naked eye. The cysts were lined with a single layer of flat angular cells resembling endothelium. In certain places, however, especially in a definite area in the largest cyst, small masses of new growth projected into the cavity. It was thought that the tumour was probably a lymphangioma, with small nodules of endotheliomatous new growth in the walls.

Mr. J. H. TARGETT and Mr. H. T. HICKS gave an account of two cases of Malignant Embryoma of the Ovary, including references to the recent literature of the subject. It was remarked that such growths were usually included in the group of teratomata but on account of their close relationship to the dermoid tumours of the ovary Mr. Targett and Mr. Hicks preferred the title of malignant embryoma. They offered the following conclusions:—1. Malignant embryomata of the ovary are rare. They usually occur in young adults but may be met with in childhood. 2. The tumours may attain a large size; they are usually pedunculated and devoid of adhesions unless the pedicle has become twisted. 3. Secondary growths are frequently restricted to infection of the peritoneum. They may present the same composite structure as the primary growth or be wholly composed of sarcomatous elements. 4. Pain and ascites are constant symptoms; ascites may develop early, even before actual infection of the peritoneum. In several instances a diagnosis of twisted ovarian cyst has been made. 5. Ovarian tumours exhibiting an irregular disposition of embryonic elements are very liable to be malignant.

Dr. R. BOXALL showed an Extra-uterine Gestation Sac which had ruptured in the fifth month of pregnancy.—Dr. G. E. HERMAN said that after the mid term of pregnancy rupture of the sac became rarer and rarer as the months went on. There was a broad contrast between the first and second half of ectopic pregnancy: in the first half rupture was frequent and the risk of operation was small; in the second half rupture was rare and the risk of operation was great.

Dr. J. S. FAIRBAIRN showed the Uterus and Appendages removed by abdominal hysterectomy from a woman, aged 50 years, as a well-marked example of arterial degeneration. The naked-eye appearance of the uterus suggested a general fibrosis. Further examination showed a distinct increase of fibrous tissue and calcification of some of the uterine arteries. This condition was associated with menorrhagia and consequent anæmia and loss of strength.—Dr. H. M. MACNAUGHTON-JONES remarked that in these cases of calcification it was noticed that there was previous hyaline degeneration.—Dr. AMAND J. M. ROUTH asked whether there was any explanation of the menorrhagia, which was a constant symptom of these cases. With the atrophic mucosa and the sclerosed arteries a diminished rather than an excessive menstrual loss might be expected.

Mr. HERBERT J. PATERSON showed a Loop of Small Intestine Adherent to the Stump of an Ovarian Tumour and remarked that the condition found might be partly accounted for by the presence of chronic peritonitis at the time of operation, but the specimen emphasised the importance of leaving the pedicle with a smooth surface free from knots and especially of obtaining early movements of the intestine.—Dr. HERMAN asked whether anyone had ever opened an abdomen within a few weeks after abdominal section without finding adhesions. He himself had never met with, heard of, or read of such a case. Adhesions were the immediate invariable result of abdominal section and in course of time were absorbed.—Dr. MACNAUGHTON-JONES said that he preferred giving saline instead of calomel when it could be tolerated. He thought the mistake was frequently made of being over-anxious with regard to the bowel.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—A Clinical Study of Influenza in the Epidemic of 1904–05.—On the Urine Separator of Luys.—Post-anæsthetic Sickness.

A MEETING of this society was held on July 5th, Professor J. CHIENE, the President, being in the chair.

Dr. W. ALLAN JAMIESON showed a case of Granulosis Rubra Nasi. The patient, a boy, aged nine years, who was healthy enough though with rather feeble peripheral circulation, as shown by his hands and feet readily becoming cold in winter, went to the Royal Infirmary on June 17th, 1905. With the exception of slight catarrhal jaundice three years since he has apparently had no illness. Two and a half years ago his mother remarked that the lower half of the nose was distinctly reddened, and beads of sweat poured from it, especially at meal times. There has been little change since then. The redness is made up of fine punctiform elevations, imparting a somewhat granular aspect. Droplets of perspiration stud the part. There were no subjective sensations. On the right side of the nose near the root there is a small spider nævus. An ointment containing sulphur and salicylic acid in vaseline was directed to be rubbed in twice a day, and now (July 6th) the redness is less and the sweating diminished, though the weather has been hot. The disease in all respects corresponds to the description of Jadassohn, MacLeod, and others.

Dr. W. T. RITCHIE exhibited for Dr. G. A. GIBSON two cases of Syringomyelia. In the first case, that of a man aged 55 years, the main features were complete anæsthesia to every form of sensory stimulus over those areas corresponding to the segmental distribution of the eighth cervical and first dorsal segments on the right side and the eighth cervical and first to fourth dorsal segments on the left side, bilateral dissociated anæsthesia from the fifth to the ninth dorsal segments, wasting of the muscles of the thenar eminences in both hands, with fibrillary tremors in those muscles, and a double extensor response. The second case, that of a man aged 44 years, presented dissociated anæsthesia over the left upper and lower extremities, the left side of the face and of the trunk, paralysis of the right cervical sympathetic, and an extensor response on the left side but no wasting or paralysis of voluntary muscles.

Mr. F. M. CAIRD showed: (1) a patient after Excision of the Rectum by Kraske's Method; and (2) a patient after recovery from Purulent Appendicular Peritonitis with Paralysis of the Gut.

Mr. J. M. COTTERILL showed a case of Tumour of the Parotid and another with Perforating Ulcer.

Mr. CHARLES W. CATHCART exhibited (1) a patient after Suture of a recently fractured Patella; (2) a patient after Wiring of a Fractured Femur on account of malposition;

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Tubercle of the Iris.—Sympathetic Ophthalmia.—Glioma in More than One Member of the Same Family.—Microphthalmos with Orbital Cyst.

THE annual general meeting of this society was held on July 7th, Mr. JOHN TWEEDY, the President, being in the chair.

Mr. M. S. MAYOU read a paper on Secondary Tuberculosis of the Iris with Spontaneous Rupture of the Lens Capsule. The patient was a boy, aged three years. For some time previously he had been attending the hospital with tuberculous dactylitis. Three weeks before attending the ophthalmic department of the London Hospital his eye had become inflamed. The left eye showed a typical conglomerate tubercle in the upper part of the iris. The pupil was occluded by exudation so that the condition of the underlying lens could not be made out. There was no history of injury. Directly after his admission to the hospital he developed three smaller masses in the iris at the lower part. Under treatment the condition improved and he was sent to the convalescent home; a month later he returned to the hospital with a small hæmorrhage into the anterior chamber and his eye was removed. On pathological examination the mass in the upper part of the iris was seen to be adherent to the posterior surface of the cornea which was buckled inwards by the pull of the underlying cicatricial tissue. Descemet's membrane was perforated and there was some round-cell infiltration of the substantia propria. The iris in the upper part consisted of a mass of fibro-cicatricial tissue adherent to the cornea in front and to the anterior and posterior capsule of the lens behind containing giant cells, but no epithelioid cells or tubercle bacilli were found. There were also several masses of round-cell infiltration in the lower part of the iris making their way outwards towards the canal of Schlemm —the most usual situation for the disease to perforate the globe. The anterior capsule of the lens showed a large gap in its continuity, evidently produced by the softening effect of the tubercle, followed by the cicatricial contraction in the anterior synechiæ. The retina showed several masses of round-cell infiltration similar to that seen in the lower part of the iris, evidently of a tuberculous nature. The special points of interest about this case were: 1. The unusual situation at which the tuberculous mass had invaded the cornea. 2. The spontaneous rupture of the lens capsule. 3. The nature of the exudation into the retina. 4. The general tendency towards cicatrisation in the lesion—a fact which, taken in conjunction with the series of cases reported by Sandford of tuberculous iritis associated with pulmonary tuberculosis, held out hope of successful treatment by tuberculin (Wright's method).—Mr. SIMEON SNELL suggested the injection of iodoform into the anterior chamber as an efficient remedy for tuberculous iritis.—Mr. H. E. JULER considered the presence of giant cells scarcely sufficient proof of tubercle and inquired into the condition of the retina.

Mr. SIMEON SNELL (Sheffield) related the following cases of Sympathetic Ophthalmitis showing itself after Enucleation. The first was that of a boy, aged ten years, who having been knocked down by a horse and trap was picked up unconscious. Besides injuries to the head he had sustained a large wound at the inner side of the sclerotic, reaching forwards through the ciliary region to the cornea. The accident occurred on April 4th, 1904, and enucleation of this eye was performed on April 20th. On May 9th there was sympathetic ophthalmitis, and judging from the account given it must have been present since the 5th. It was a severe instance of the disease showing a great tendency to recurrence but ultimately the patient was able to find his way about and to read large type. At the same time another case was under observation, that of a man, aged 26 years. The left eye had been injured by a kick on June 13th; it had been enucleated elsewhere on June 29th. The injury involved the corneo-scleral junction. He went to Mr. Snell on July 29th when there was marked sympathetic ophthalmitis in the right eye; it had begun on July 22nd. It was a severe type of the disease, the ultimate result being practical blindness. Mr. Snell referred to another case, which he had not previously recorded, of a girl, aged about ten years, for which, however, the dates could not be given precisely. He also mentioned that he had published an instance in the Transactions of the society for 1882. In this, sympathetic ophthalmitis showed itself 32 days after the enucleation and 106 days after the date of injury. The disease was of a mild form and perfect vision was recovered. Mr. Snell mentioned that there were thus four instances occurring in his practice after enucleation. One was of a mild form with perfect recovery and the other three were of a severe type, two becoming totally blind whilst the third partially recovered vision. The report of the society's committee stated that usually the disease in such instances was of a mild form and that out of 30 cases 18 completely and three partially recovered, while nine became blind. Mr. Snell further noted that two of his cases were children, one a boy, and one a girl, aged ten years, the remaining two being men both aged 26 years. The time elapsing after enucleation and the disease showing itself was 16, 23, and 32 days and the period after the original injury was 32, 40, and 106 days. For the fourth case the data on these points were not precise.—The subject was discussed and cases were cited by Mr. JOHNSON TAYLOR (Norwich), Mr. A. W. ORMOND, Mr. D. MARSHALL, Mr. W. B. LAWFORD, Mr. H. SECKER WALKER, Mr. R. W. DOYNE, and Mr. SNELL.

Mr. SNELL also related a case of Sympathetic Ophthalmitis in which normal vision was restored in the exciting and in the sympathising eye. The left eye was injured on Sept. 8th, 1904, but the patient, a man, aged 33 years, was not seen until the 19th. The fragment of steel causing the injury was about a quarter of an inch long and of the same width. The iris prolapsed through a wound in the upper part of the cornea, passing for a little distance into the ciliary region. The prolapsed iris was immediately excised and the edges of the wound were cleared as far as possible of any portions of iris. Subsequent progress was excellent and the eye has not occasioned any further trouble. On Oct. 12th the right eye was noticed by the patient to be a little red. On the 17th there was distinct iritis, the pupil acting very imperfectly to atropine.. The next day it was noted that it was a severe instance of sympathetic ophthalmitis. It was not until the middle of November that the eye began to look white and the pupil to dilate fully. Since then, however, progress has been satisfactory, there have been no recurrences, and vision in each eye is $\frac{6}{5}$, and J.1 is read perfectly. Mr. Snell referred to a case recorded by him in the Transactions of the society for 1883 in which the sympathetic ophthalmitis had resulted from an injury not at all unlike that in the present instance, the injury being caused by a packing needle which had penetrated the left eye at the sclero-corneal junction. The sympathetic iritis in this case, however, was of a very mild form compared with that now related.

Mr. SNELL referred to the paper which he read before the society last year and in which he related an instance of Glioma occurring in two members of the same family. Only three observers had then placed cases on record. He now related a further case which this year had come under his notice. The patient was a male child, aged two and a quarter years, and glioma was present in each eye. It had been noticed first in the left eye a few months after birth and in the right eye within the last few months. It was ascertained that the only other child of the parents was a girl, born in 1897, who was similarly affected with glioma in both eyes which proved fatal. Inquiry left no doubt as to the disease being glioma. In the instance now related the most affected eye was first enucleated and submitted to microscopical examination. Mr. E. Treacher Collins reported it to be a glioma. Later, the second eye was removed and examined with a similar result. Mr. Snell mentioned that the child, particulars of whom were related last year, was still alive and well.

Mr. R. R. CRUISE described a case of Microphthalmic Cyst of the Orbit. The patient, a woman, aged 24 years, had from birth a swelling in the left orbit associated with a microphthalmic eye pushed into the upper and outer quadrant. Trouble was caused by variation in the size of the cyst. The orbital contents were eviscerated and during the operation some clear fluid escaped. The patient herself made a good recovery. Microphotographs were shown which displayed the pathological changes in the globe and their

Mr. Bellamy Gardner, and other authorities. The effect produced by "mixed drinks" at a banquet could not be regarded in any way as analogous. Ethyl chloride formerly always existed to the extent of a small percentage in well-known brands of chloroform and of late years was being added in order to hasten the induction of anæsthesia. It was therefore absurd to suppose that the effect produced by the drug *in sequence* could materially differ from the effect when *in mixture*. The influence of the various operations was dealt with in detail and as regards age young people from 12 to 15 years old were found to suffer most frequently from after-sickness, the rate of frequency steadily diminishing from the fifteenth to the eightieth year. Females were more often troubled with sickness than males in the proportion of five to four. As regards treatment little was to be done. Drug treatment was merely palliative, the measures advocated in text-books being practically useless. Drinks of warm or hot or effervescing waters were of service, as was albumin water. In bad cases washing out the stomach was of great use. Deprivation of fluids after operations was often a mistake and overdone. Patients had a natural thirst after purging and loss of blood which should to some extent be gratified. The rational line of treatment lay in stimulating the skin, kidneys, and bowels to throw whatever anæsthetic was used out of the body tissues as soon as this could be effected.

Reviews and Notices of Books.

Handbuch der Geburtshülfe. (*Handbook of Midwifery.*) Edited by F. VON WINCKEL. In three vols. Vol. I., Second Part. With numerous plates and illustrations. Wiesbaden: J. F. Bergmann. Glasgow: F. Bauermeister. 1904. Pp. 643. Price 13*s.* 9*d.*

A NOTICE of the first volume of this handbook appeared in THE LANCET of Feb. 27th, 1904, p. 583, and, as we pointed out at the time, the fact that it is edited by Professor von Winckel is a proof that it is a work of the very highest importance and value. The second volume more than sustains the high opinion that we formed of the first and contains a great deal of information of the utmost value. It is devoted to a consideration of the physiology and dietetics of pregnancy and the physiology and dietetics of labour. The word "diätetik" in German means rather more than we are accustomed to assign to it in English, for under the dietetics of pregnancy are included the treatment of the minor disorders of that condition and the preparation of the patient for labour. The dietetics of labour, too, include the avoidance of rupture of the perineum and the treatment of the umbilical cord after the delivery of the child.

The first chapter by F. Skutsch is concerned with the Examination of the Pregnant Patient. It contains a very good account of the various methods of external and internal examination, the diagnosis of pregnancy from other conditions simulating it, the important points in the diagnosis of a first and of subsequent pregnancies, and the determination of the period of pregnancy and of the size of the child.

P. Strassmann has written the second chapter on Multiple Pregnancies and discusses not only their mode of development but also many questions connected with the various pathological states which may be associated with, or may be dependent upon, the presence of such a condition. The interesting question of the relationship of the occurrence of multiple births to the general fertility of women is considered as also are the effect of heredity, and the relationship between the frequency of twin pregnancies and that of triplet or quadruplet. The author calls attention to various facts which suggest that tendency to multiple births shows an atavistic attribute in the human race, citing amongst other things the disproportionately frequent association with it of polymastia and its more frequent occurrence in animals low in the scale of development.

The section dealing with the Treatment of the Minor Disorders of Pregnancy is contributed by von Herff; and E. Bumm writes on the Preparation of the Patient for Labour. In the second portion of the book O. Schaeffer describes the nerve centres of the uterus, the expulsive forces, the resistances, and the course of labour. The description of the bony pelvis and the soft parts is by H. Sellheim and is full and very well illustrated. At the end of the chapter on the Attitude, Presentation, and Position of the Fœtus Seitz concludes that its attitude and position are primarily due to the form of the uterus and its activity; whilst the frequency of vertex presentations depends chiefly on the relationship between the shape of the uterus and that of the child, the direction in which the uterine forces act, the great mobility of the fœtal head, and the preponderance in size of the upper uterine segment over the lower segment. Eighty pages are devoted to the section on the Mechanism of Labour written by M. Stumpf and he gives a very voluminous literature of the subject.

O. Sarwey writes Chapter VIII. dealing with the Diagnosis and Conduct of Labour and also treats of the prevention of tears of the perineum and the ligature and treatment of the cord after the delivery of the child. In discussing the question as to whether the antiseptic or aseptic management of labour is the better K. Menge declares in favour of asepsis. He holds that the untouched genital canal is aseptic and requires no disinfection and that the antiseptic treatment of labour is under all conditions objectionable. He believes it will only be by the strict avoidance of infection of the hands, by abstinence from midwifery practice when the hands have been infected, and by the immediate stopping of any such practice in cases where any patient develops signs of septic infection, combined with rational disinfection of the hands and the use of sterile coverings for them, the avoidance of any unnecessary interference with the patient, and the careful sterilisation of all the materials used, that the danger of infecting lying-in women with puerperal fever will be avoided.

A very interesting contribution is that of G. Klein on Walcher's position. He gives a historical sketch of the subject and discusses fully the advantages to be obtained from its use in cases of difficult delivery. There is no part of the management of labour in which so many mistakes are likely to be made as in that of the third stage. The tendency is to express the placenta too soon after the birth of the child and this practice frequently leads to the retention of some portion of the placenta or membranes. A. Lindfors gives a very interesting account of the four chief methods of treating this stage and sums up in favour of the so-called Dublin method. The last chapter in the book is by P. Strassmann and in it he considers the progress and course of labour in multiple pregnancies including the various abnormalities which may be met with.

As we have said, the present volume fully comes up to the high standard of the first. The book is the most important work which has appeared for some years on the subject of midwifery and when completed will form a handbook of the greatest possible value and one that will be indispensable for every teacher of this branch of medicine.

Exercises in Practical Physiology. By AUGUSTUS D. WALLER, M.D. Aberd., F.R.S. Part II., Exercises and Demonstrations in Chemical and Physical Physiology. By A. D. WALLER and W. LEGGE SYMES. London: Longmans, Green, and Co. 1905. Pp. 79. Price 2*s.* 6*d.* net.

THESE exercises consist of eight chapters dealing successively with the blood, circulation, carbohydrates and salivary digestion, proteids and gastric digestion, fat and pancreatic digestion, milk (bile and muscle), urine, and respiration. This little work forms a companion to the and (3) a patient after Elevation of a very Extensive Depressed Simple Fracture of the Skull.

Mr. J. W. STRUTHERS demonstrated: (1) a patient after Radical Cure of Inguinal Hernia under local anæsthesia; (2) a patient after Excision of the Astragalus for Compound Subastragaloid Dislocation, &c.; and (3) a patient after Unusual Fracture of the Ulna.

Mr. H. ALEXIS THOMSON exhibited a patient after operation for Arterio-Venous Aneurysm in Scarpa's Triangle, followed by secondary hæmorrhage, ligation of the external iliac artery, and gangrene of the limb.

Mr. COTTERILL exhibited (1) a series of Gall-stones; and (2) a series of Damaged Semilunar Cartilages from the Knee.

Mr. THOMSON exhibited (1) a specimen from a case of Cholecystectomy for Gall-stones and Pendulous Gall-bladder; and (2) Enlarged Prostate and Vesical Calculus removed by suprapubic operation.

Dr. MICHAEL DEWAR read a paper on a Clinical Study of Influenza in the Epidemic of 1904–05. He said that the first trustworthy account of an influenza epidemic was that of 1510. Records of several epidemics were met with then. One in 1732 spread over the whole of Europe and part of America; another was recorded in 1785; while another in 1803 invaded the whole of Great Britain. An epidemic in 1847 attacked London in a single day and affected over half a million of people. Even at that time it was believed to depend on a specific contagion. 30 years' ago physicians had not much experience of it. There had been at least three epidemics in Edinburgh during recent years, 1889–90, 1898, and 1904–05, each exhibiting the same types but the predominating type differing on each occasion. The epidemic of 1889–90 was chiefly of the nervous type and was very severe, many cases ending in melancholia, insanity, and death. In the epidemic of 1898 the cardiac and pulmonary type predominated. Both of these epidemics attacked the middle-aged and elderly, children escaping with only a few exceptions; while in the epidemic of 1904–05 children were the chief sufferers. The main difficulty at first was that of diagnosis to separate true influenza from colds and catarrhs of various organs of the body. The method adopted was that of exclusion and was perhaps the best short of examining the bronchial secretion of every patient bacteriologically. The majority of cases in the recent epidemic in Edinburgh occurred during the 30 days from mid-January to mid-February. The onset was gradual, beginning in the last weeks of December and ending at the close of February—a period altogether of about eight weeks. As regards etiology, most writers were agreed that the disease was due to Pfeiffer's bacillus. Leichtenstern distinguishes between true epidemic influenza due to Pfeiffer's bacillus and pseudo-influenza, which is commonly called "grippe," of unknown etiology. The epidemics which came most under Dr. Dewar's notice occurred at the close and at the beginning of the year. In recent epidemics three principal types were noted: (1) cardiac and pulmonary, (2) gastro-intestinal, and (3) nervous. Each case presented symptoms common to all, yet there were predominating symptoms sufficiently well marked in order to classify them. The diagnosis was arrived at by considering the manner of onset, temperature, facial expression, erratic pulse, dry brownish tongue, &c. Coryza was not frequently observed as is stated in text-books; it was more frequently absent than present. In the cardiac and pulmonary types both sexes of adults and children were fairly equally attacked. In the cardiac cases the temperature varied from 99° to 102·5° F. for the first three days; then it ranged from 99° to 100° for about a week, becoming normal after another week. The heart was feeble and irregular, with frequently a soft-blowing mitral systolic murmur, while the pulse was quick, soft, and compressible. Usually a dry cough accompanied the attack. In pulmonary cases, usually bronchial, the temperature was, as a rule, higher—104° and upwards. A typical cardio-bronchial case was recorded the chief features of which were sudden onset, severe headache, and pains in the chest and shoulders; a temperature of 104·5°; a sharp rapid pulse of 140; and respirations of 20. At first nothing abnormal was found in the chest; then pains developed in the stomach, under the left arm, and over the right shoulder; there were no rash and no diarrhœa; the tongue was dry and brown with a darker band down each side. The latter sign was very characteristic. The temperature continued very irregular from 100° to 104·5°; it was not of the swinging type as in gastro-intestinal cases but often reached the maximum in the morning and the minimum in the evening. After four days bronchial symptoms appeared with the moist sounds over the left lung behind. These symptoms continued for the next ten days, after which the temperature fell to 99° and 100°, with an occasional leap to 103° or 104° for a few hours, and by the twenty-first day the temperature had become normal. The gastro-intestinal type was observed chiefly amongst children, the prominent symptoms being abdominal pain with diarrhœa coming on four or five days after the onset. In these cases the temperature was swinging and more regular as regards morning and evening than the cardiac form. A very characteristic symptom in this form was pain in the right hypochondriac region just over the liver and over the right shoulder. Diarrhœa with stools of a greyish-green colour with little green masses like discs of sulphate of iron scattered through them usually commenced about the fifth day and convalescence was initiated about the tenth or twelfth day. The nervous type was almost confined to adults of both sexes. The prominent symptoms were intense frontal and biparietal headache, conjunctival and nasal catarrh (more frequent in this type), pains, and great depression of spirits. The temperature never exceeded 103·5° and reached this only during the first two or three days. This was followed by a sudden drop to subnormal, 97° or 96·5°, rarely rising morning or evening for from a week to ten days. As a rule the patients were very ill during this period but improved as the temperature rose to normal. Convalescence was usually protracted. A case of a mixed type in an elderly female was recorded. The sequence was: influenza, pleurisy on the seventh day, pneumonia on the thirteenth day, sepsis on the thirty-fourth day, heart irregular about the fortieth day, melancholia a few days later, gastro-intestinal symptoms about the fiftieth day, and death on the sixty-ninth day from heart failure. The prognosis was generally good in the first two types but not so good in the third. Treatment consisted chiefly in good nursing and dieting. In conclusion, Dr. Dewar said (1) that influenza epidemics were shown to have been recurring every seven or eight years; (2) that they always occurred during the winter season; (3) that the period covered was from eight to ten weeks; (4) that coryza ushered in the disease in a small proportion of cases; and (5) that the gastro-intestinal forms in recent epidemics were invariably characterised by pain underneath the liver and over the right shoulder.

Mr. CAIRD read a paper on the Urine Separator of Luys. He drew attention to the care necessary in the selection of a good instrument and to the method of its employment, noting that it had to be sterilised carefully. The method of introduction in the male and female was described and the value of indigo-carmine as showing the complete separation of the urine was alluded to. Several illustrative cases were narrated as well as the results obtained.

Dr. T. D. LUKE read a paper on Post-anæsthetic Sickness: its Cause and Treatment. He pointed out that the after-sickness often constituted the most trying part of a surgical operation. The factors influencing the occurrence of after-sickness were the following: the nature of the anæsthetic used; the operation performed; its duration; the skill with which the anæsthetic is given; the care with which the patient is prepared; the patient's condition at the time of the operation as regards digestive tract, &c.; age, sex, temperament, habits, and constitution also having considerable influence in the matter. The statistics prepared by the British Medical Association anæsthetic committee were made use of together with those of Mr. Marcus Gunn. Dr. Luke found that while actual occurrence of sickness was more frequent after ether it was brief in duration and very seldom so severe as that seen after chloroform in a number of cases. About 45 per cent. of cases are sick after ether and about 20 per cent. after chloroform. Chloroform sickness is due to the markedly inhibitory action of chloroform on the metabolic processes and may be regarded as a mild kind of chloroform toxæmia of a subacute nature where the toxic action of the drug does not go so far as to produce the gross cellular stages described by Guthrie, Stiles, and others. Dr. Luke stated that sickness after ethyl chloride occurred in from 15 to 20 per cent. of cases and found that statements made as to sickness being more severe after mixtures and sequences, such as ethyl-chloride-ether sequence and ethyl-chloride-C.E. sequence, were not based on fact but on prejudice, and in support of his remarks gave the personal opinions of Dr. F. W. Silk, many counties. A report of the latest commission appointed to inquire into the pathology, and so on, of the disease has been promised shortly. Anthrax is largely increasing and one factor in its spread is the habit, through ignorance of the methods of propagation of the disease, on the part of the average farmer of opening the carcass of a cow (which has died suddenly) to try to find out the cause. If instead of doing this he would report to the local veterinary authority fewer cases would occur as a sequel to the first death.

Epizoötic lymphangitis, which has been imported into England with the returned army horses from South Africa, has, on account of its tedious course when treated and its contagiousness, caused the Government to issue a pamphlet to every member of the veterinary profession in the British Isles. This pamphlet describes the differences between this disease and farcy. Glanders is admittedly on the increase and it is time that some radical measures were taken to control this disease. In 1894 there were only 502 outbreaks reported but in 1904 these had increased to 1529 and 2658 horses were killed as glandered. More power ought certainly to be given to the veterinary inspectors to test the in-contact horses with mallein, as by this agent an almost infallible diagnosis can be made within 24, or at most 48, hours. The expense, although great the first year, would not be excessive if allowed to be spread over a period of years; and where a preventable disease, which also causes the deaths of numbers of human beings each year, is concerned, the cost ought certainly not to be considered too seriously as a reason why it should not be taken thoroughly in hand. Sheep scab is favourably reported upon and rabies is non-existent. The latter is a cause for much congratulation and it is to be hoped that the present successful measures will be continued. Many other diseases are touched upon and the book is well worth a place in the library of everyone who is interested in the subject of the diseases of animals.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, K.C.B., F.R.S., and J. N. LANGLEY, F.R.S. Vol. XXXII., Nos. 3 and 4. May, 1905. London: Cambridge University Press Warehouse. Pp. 127. Price 8*s.*—This part contains the following articles: 1. The Fractional Hydrolysis of Optically Inactive Esters by Lipase, Part II., by H. D. Dakin. 2. Observations upon Fibrin Ferments in the Venoms of Snakes and the Time Relations of their Actions, by C. J. Martin. 3. On the Formation of Fatty Acids from Lactic Acid when fused with Caustic Alkalies, by H. S. Raper, 1851 Exhibition Scholar. 4. Note on Neumann's Method of estimating Chloride, by W. Legge Symes. 5. The Regulation of the Lung Ventilation, by J. S. Haldane and J. G. Priestley, with 11 figures in the text. The authors show that at a constant atmospheric pressure the air in the alveoli of the lungs contains a practically constant percentage of carbon dioxide but in different individuals this percentage differs. Within limits with varying atmospheric pressure the alveolar percentage varies in each individual inversely as the atmospheric pressure, so that the alveolar carbon dioxide pressure is constant while the oxygen pressure varies widely. The respiratory centre is exquisitely sensitive to any rise in the alveolar carbon dioxide pressure, a rise of 0·2 per cent. of an atmosphere being sufficient to double the amount of alveolar ventilation. When the oxygen pressure in the inspired air falls below about 13 per cent. of an atmosphere the respiratory centre begins to be excited by want of oxygen. During muscular work the alveolar carbon dioxide pressure is raised slightly with a corresponding large increase in the lung ventilation. The amount of air breathed per minute and per unit of body varies widely in the same individual and still more widely in different individuals. 6. The Separation of Proteids, by H. C. Haslam, formerly John Lucas Walker student. 7. On the Products of Digestion of the Proteolytic Enzyme of the Spleen acting in an Alkaline Medium, by E. P. Cathcart. 8. The Effect of Cold Narcosis on Reflex Action in Warm-blooded Animals, by Sutherland Simpson and Percy T. Herring. 9. The Effects of Acids upon Blood, by Charles E. Ham and Hermann Balean. 10. Observations on the Munchi Arrow Poison, by Alfred Fröhlich. The Proceedings of the Physiological Society for Feb. 25th and March 18th are also contained in this part.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

EUDRENINE.

(PARKE, DAVIS, AND CO., 111, QUEEN VICTORIA-STREET, LONDON, E.C.)

EUDRENINE is described as a local anæsthetic and hæmostatic for the painless and bloodless extraction of teeth and for use in general surgery. It contains in each cubic centimetre 0·01 gramme of the anæsthetic beta-eucaine hydrochloride and 0·033 milligramme of the powerful hæmostatic adrenalin chloride (Takamine). For tooth extraction eudrenine is used undiluted by injecting into the gum ten minutes before operating the contents of one or two "ampoules," equal to eight or 17 minims, according to the number of teeth to be extracted. For small surgical operations eudrenine is used undiluted but when a large area is required to be anæsthetised it is diluted with four volumes of "physiological" sodium chloride solution. The advantages of beta-eucaine over cocaine are well known and the object of combining it with adrenalin is to contract the blood-vessels so that not only is the action of the anæsthetic localised but the operation may be performed without bleeding. The result is that only a small quantity of the anæsthetic is required.

(1) SUGARLESS JAM; AND (2) STARCHLESS BISCUITS.

(CALLARD AND CO., 74, REGENT-STREET, LONDON, W.)

According to our examination both of these preparations may be given to patients in whose cases sugar is prohibited. In the jam we found a trace of sugar which, according to the phenyl-hydrazine test, appeared to be milk sugar, since the small quantity of crystals produced had the characteristic appearance of lactosazone. There was also a slight reduction with Fehling solution. The jam is sweet to the taste owing to glycerine and has the consistence of ordinary jam. The flavour of the sample submitted to us was that of black currant. The colouring is rather brilliant but of a harmless kind. The biscuits gave absolutely negative evidence as regards the presence of starch, the chief constituent being proteid which to some extent is soluble in water. Reactions were obtained with the solution characteristic of milk proteid.

PURE GRAPE PORT.

(HUNT, ROOPE, TEAGE, AND CO., OPORTO, AND 3 AND 4, WATER-LANE, GREAT TOWER-STREET, LONDON, E.C.)

This is an undoubtedly genuine port wine and as the following analysis shows is of a robust and an invigorating character. It is more suitable for invalid purposes than as an after-dinner wine. The analysis was as follows: extractives, 14·30 per cent.; mineral matter, 0·25 per cent.; sugar, 12·50 per cent.; volatile acidity reckoned as acetic acid, 0·066 per cent.; fixed acidity reckoned as tartaric acid, 0·21 per cent.; and alcohol, by weight 19·58 per cent., author's systematic work, to which reference is made and from which some of the illustrations are reproduced. On the whole the experimental part seems to us to be fuller than the more purely chemical sections. All the directions are precisely given and can be easily followed by the student in the laboratory. Students who have to present themselves for a practical examination involving the subjects discussed will find this book useful and so also will students in a properly equipped laboratory. Naturally, a fair number of the experiments must be in the nature of demonstrations by the teachers rather than the actual work of the student of physiology. In these cases this is stated and full details are given.

Methods of Morbid Histology and Clinical Pathology. By I. WALKER HALL, M D. Vict. (Manchester), and G HERXHEIMER (Wiesbaden). London and Edinburgh: W. Green and Sons. 1905. Pp. 290.

A BOOK of this type, designed for the requirements of students and pathologists working in hospitals and institutes, makes no claim to originality. Indeed, it consists largely of recipe methods taken from well-known text-books, while the authors state in particular their indebtedness to the work of Schmorl—i.e., "Die Pathologisch-Histologischen Untersuchungsmethoden." Of this work, the second edition (1901) is before us. The authors state that the details of methods they record were, except in a few cases, obtained from the original papers and a list of papers is appended. As one of the authors was assistant to the late Carl Weigert for several years it is appropriate that their book is dedicated to his memory.

There is nothing new in the chapters devoted to the examination of fresh objects, freezing, fixation, hardening, and decalcification; nor, indeed, is there in those on imbedding, sectioning, clearing, mounting, or staining. Substantially the same methods are applicable to normal animal histology and are to be found in text-books on that subject. In the chapter on special cell and tissue structures the methods are in some respects like those adopted in Schmorl's work in the chapter dealing with methods for demonstrating special constituents of cells and tissues.

In Chapter XII. special tissues and organs are dealt with and that on the nervous system is naturally crowded; in fact, there are too many methods bearing the names of their authors—modifications of some fundamental method. It would have been better had the authors been able to give the aspiring tyro some definite statements as to the comparative virtues of these modifications.

The methods regarding bacteria, moulds, and other fungi, and animal parasites occupy more than 30 pages, while to clinical microscopy eight pages are given. It will be seen that the word "clinical pathology" is taken in a somewhat restricted sense; and only those methods which a pathologist may require during his routine work are given.

The book will be found useful for reference but the student may have difficulty in knowing which of the numerous methods he ought to select.

Health and Disease in Relation to Marriage and the Married State. Edited by Geheimer Medizinalrat Professor Dr. H. SENATOR and Dr. Med. S. KAMINER. The only authorised translation from the German into the English language by J. DULBERG, M.D. Wurzburg, of Manchester. London and New York: Rebman, Limited. Vol. II., pp. 777. 1905. Price, for two vols., 30*s*. net.

IN our issue of Oct. 8th of last year we reviewed the first volume of this work. The second volume is now before us; it is divided into 14 chapters which treat respectively of (XIV.) Gonorrhœal Diseases in Relation to Marriage; (XV.) Syphilis in Relation to Marriage; (XVI.) Diseases of the Skin in Relation to Marriage; (XVII.) Diseases of the Organs of Locomotion; (XVIII.) Diseases of the Eyes, with special regard to Heredity; (XIX.) Diseases of the Lower Uro-genital Organs and Physical Impotence; (XX.) Diseases of Women, including Sterility; (XXI.) Diseases of the Nervous System; (XXII.) Insanity in Relation to Marriage; (XXIII.) Perverse Sexual Sensations and Psychical Impotence; (XXIV.) Alcoholism and Morphinism in Relation to Marriage; (XXV.) Occupational Injuries in Relation to Marriage; (XXVI.) Medico-Professional Secrecy in Relation to Marriage; and (XXVII.) the Economic Importance of Sanitary Conditions.

The section on gonorrhœal diseases is from the pen of Professor A. Neisser of Breslau. It is, we think, the most important in this volume and is well worthy of study. Professor Neisser points out that there is hardly another disease dealt with—not even syphilis—that has such far-reaching and momentous consequences for the married state as gonorrhœa. The dangers to the female emanating from chronic gonorrhœa in the male are brought as prominently forward as they deserve to be. The teaching is that when marriage is contemplated, as all post-gonorrhœic residual affections are not infectious, it is necessary to subject every individual who presents any abnormal symptoms derived from a former gonorrhœa to a special examination for the purpose of ascertaining whether these symptoms are still of an infectious nature. The examination for gonococci alone enables the physician to say whether marriage should be permitted and this examination should be made as searching as possible. In the case of men it is necessary to examine not only the superficial secretion of the anterior urethra and that of the posterior urethra—if possible separately—but to endeavour to bring to light the secretion situated in the crypts between the folds of the urethral mucous membrane and to examine it. Careful search must be made for the existence of preputial and para-urethral passages, of fistulæ and small abscess-cavities. In special cases it may be necessary with the help of the endoscope to look also for gland-like epithelial swellings lying in the urethra. Professor Neisser examines every case of chronic urethritis by means of Gram's method, and when the question of marriage is under consideration he makes use of the cultivation-method also.

The chapter on Medico-Professional Secrecy is written from the point of view of a German medical practitioner and is, therefore, not applicable to English and American conditions, but it is interesting reading. The diversity of medical practice very often places medical men in the unpleasant situation of having to choose between the injunctions imposed upon them by the different laws and the dictates of their own consciences. In Germany the law admits of no exceptions and a medical man has no right to divulge what has become known to him in his professional capacity, no matter how serious the consequences may eventually turn out to be.

Dr. Dulberg is to be congratulated on having completed his task and on having given us a translation of the most comprehensive work on a subject which is of interest to every practitioner.

Report of the Board of Agriculture and Fisheries for 1904. London: Darling and Son. Price 11*d*.

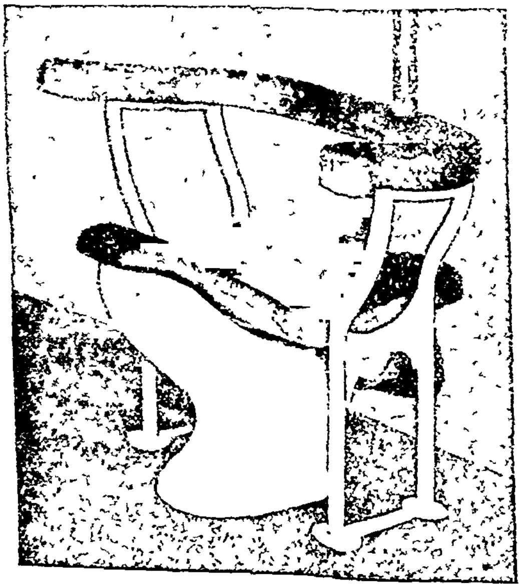
THE report of the work done by this department of the Government is one of the most hopeful which has been issued for some years. Mr. Cope, M.R.C.V.S., the chief veterinary officer, is able to congratulate the country on the success which has prevailed in regard to certain cattle scourges, particularly foot and mouth disease and pleuro-pneumonia, neither of which, we hope, will ever reappear in Great Britain. Swine fever, too, is on the decrease, although still far too widespread and met with in very

New Inventions.

TWO NEW WATER-CLOSETS.

(1) THE "NATURAL" WATER-CLOSET AND SEAT.

IT has been said that not a few human disorders, and more particularly those connected with the abdominal region, arise from the unnatural attitude commonly adopted by civilised man in the act of defæcation. The defects from an anatomical point of view of the ordinary water-closet pedestal and seat in general use are so well known and recognised that only the advent of a really scientifically designed closet-seat justifies the re-discussion of the question. The leading text-books on physiology are silent on the important part that position plays in the act of defæcation; it is, of course, interesting to the student to be aware that centres inhibiting the ano-spinal centre are situated in the base of the thalami and the upper end of the crura cerebri, but the important differences between the seated position for the evacuation of the bowels and the squatting posture are not considered. Mr. W. Arbuthnot Lane in his teaching on chronic constipation has forcibly pointed out how in the act of defæcation, in our present state of civilisation, the cæcum is driven downwards and forwards into the true pelvis, tending to drag and to displace downwards the right kidney, the individual losing in the sedentary position the enormous pressure afforded by the forcible apposition of the thigh and abdomen, which is exerted when the squatting position of uncivilised life is assumed. Not only does this squatting posture help to empty the cæcum and ascending colon but it tends to retain, both directly and indirectly, the kidney in its normal relationship. It also serves to displace the sigmoid upwards and facilitates the evacuation of its contents. The outline and general appearance of the "Natural" water-closet designed by Messrs. D. T. Bostel and Sons of 73, Ebury-street, London, S.W., are very well conveyed in the accompanying illustration, in which the closet is shown provided with a "lift up" lid and two arm rests. The height of the arms in relation to the seat renders the squatting attitude comfortable and secure. The arms are about two feet from the floor, while the lowest part of the seat is about nine inches from the floor, and the front part of it six inches higher. The posture compelled upon the user of the closet is practically identical with that assumed naturally when there is no other convenience for the purpose than the field. The peculiar construction of the pan is of great assistance to the effect of flushing, the water sweeping everything before it, and the "lift up" lid enables the pan to be used as a urinal or for the reception of slop waters. Altogether the design appears to be in conformity with the anatomical posture and requirements of the body during the act of defæcation and its use is calculated to obviate that habitual straining at stool which undoubtedly is frequently a source of abdominal mischief, as, for example, hernia.

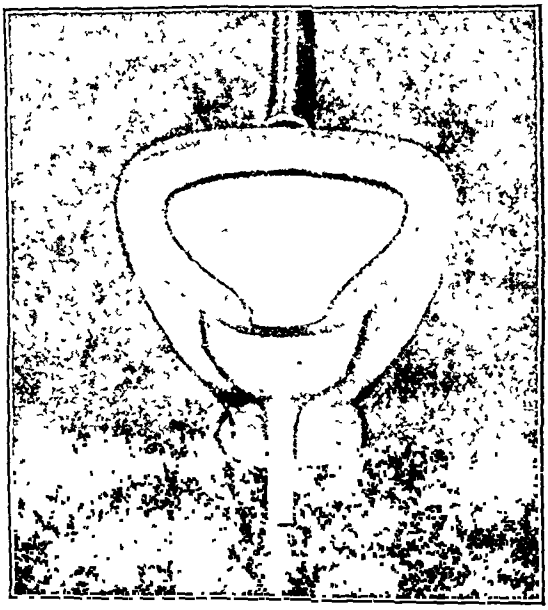


The "Natural Water-closet and Seat.

This invention will be shown in practical working order at the forthcoming exhibition of the British Medical Association at Leicester, July 24th to 28th.

(2) THE "NATURAL" SANITARY CLOSET.

THE "Natural" sanitary closet, which is the invention of Mr. E. A. Rawlence, of Newlands, Salisbury, was brought to our attention at the same time as the water-closet noticed above and the claims made for its use are almost identical. The benefits of the squatting position during the act of defæcation are described by the inventor, upon medical authority, as follows:—"The lower bowel is, in a healthy subject, self-cleansing, as in other animals. When in the natural position for defæcation the abdomen rests upon the closed thighs which support it and lessen the risks of hernia. The mechanical process of defæcation cannot take place properly while the body is in the upright sitting posture when the whole weight compresses the buttocks against a seat." The "Natural" sanitary closet is designed to meet all these disabilities. It is so shaped and of such a height as to allow defæcation to take place in an absolutely natural position in adult or child, children being especially tried by the usual shape of water-closet which allows their feet to dangle. In cases of infirmity or old age where the natural position may be difficult or impossible a specially designed flap seat can be provided so that a natural position may be attained as nearly as possible and handrails are provided to assist the user in rising from so low a position. The flap seat is so designed that it cannot well be fouled and when not in use it is fastened up to the sides of the closet. The seat slides on an iron rod fixed at a considerable angle so that when fixed full forward for an adult it is 17 inches high and when set back for a child it is 15 inches high. Sliding or revolving blocks four inches high are also provided for children using the closet in the natural position. The "Natural" sanitary closet also provides a convenient urinal and slop waste. The usage of the ordinary closet for these purposes is a frequent cause of fouling the seat. The "Natural" sanitary closet is designed to provide the same medical and sanitary benefits in country houses and cottages where water-closets are not possible and can be adapted either for a vault closet or earth system.



"Natural" sanitary closet. The flap is fastened to the side walls, where also are handrails which are not shown in the illustration.

This invention will be exhibited at the ensuing exhibition of the Royal Institute of Public Health at the Polytechnic from July 19th to 29th.

by volume 23·98 per cent., equal to proof spirit 42·03 per cent. The wine has a strong, fruity flavour. As will be seen from the above figures it is made from rich grape juice containing an abundance of saccharine matter, the grape sugar amounting to as much as 12·50 per cent. The mineral matter contained a noteworthy amount of phosphates. It is a rich, "full" wine.

CANDOL.

(CANDOL DEPOT, 20, EASTCHEAP, LONDON, E.C.)

Candol consists of a practically dry, granulated or crystalline extract of malt. We have not examined a dry extract of malt possessing such powerful diastasic activity. It rapidly converts starch jelly into a limpid fluid and finally into maltose. It is capable of dissolving its own weight of starch in a few minutes at blood heat. The convenience and advantage of an active malt extract in dry granulated form are obvious.

FRUCTOLE OF RED BONE MARROW AND GLYCEROPHOSPHATES.

(SAVORY AND MOORE, 143, NEW BOND-STREET, LONDON, W.)

The formula of this compound is an illustration of the advantages of utilising quite modern chemical and physiological knowledge. It contains phosphates in a form known to be assimilable in combination with iron and calcium and the powerful nutrient substance, red bone marrow. One ounce contains the equivalent of one drachm of red bone marrow, two grains of iron glycerophosphates, and four grains of calcium glycerophosphate. It is prepared with a fruit basis, glycerine being substituted for sugar. The flavour is pleasant. This "fructole" is, in short, an elegant pharmaceutical preparation; it keeps well and contains substances which are of well-known tonic value and which are readily utilised. "Fructoles" are also prepared of the hypophosphites, of the glycerophosphates, and of terpin and heroine.

SCOTCH WHISKY BLUE SEAL.

(HENRY SIMPSON AND CO., 6, CROSBY-SQUARE, LONDON, E.C.)

The indications of our analysis are distinctly in favour of this spirit being genuine malt whisky. Moreover it evidently possesses considerable age, for the flavour is that of a well-matured whisky. Analysis gave the following results: alcohol, by weight 38·83 per cent., by volume 46·08 per cent., equal to proof spirit 80·75 per cent.; extractives, 0·19 per cent.; and fixed acidity reckoned as tartaric acid, 0·015 per cent. The secondary constituents, or "non-alcohols" as the French chemists now term them, were as follows, given in grammes per hectolitre of alcohol present: volatile acidity reckoned as acetic acid, 26·00; aldehydes, 14·30; furfural, 2·17; ethers reckoned as ethyl acetate, 90·00; and higher alcohols, 217·00: total secondary products, 349·47. These results are in accordance with those commonly obtained with genuine old malt whisky. It may be remarked, however, that the amount of furfural is somewhat below the normal, possibly owing to the age of the spirit. Storage in sherry casks was indicated by the presence of a trace of sulphates. The flavour is mild but distinctly malty in character.

DRIED MILK.

(THE CREAMERY CO., GARSTANG.)

This is practically milk in which the entire solid constituents are retained, water only having been abstracted by a process of evaporation. Our analysis of the dry milk was as follows: fat, 30·0 per cent.; proteid, 28·66 per cent.; milk sugar, 35·34 per cent.; and mineral matter, 6·00 per cent. The powder occurs in a light, dry, crisp, flaky form. With water it yields a fluid closely resembling milk in appearance but with the fat separated. It is evident from the above analysis that the process secures the retention of the whole of the cream of the original milk. The preparation is obviously valuable for ordinary as well as special dietetic purposes.

(1) LAGER BEER; AND (2) SPECIAL STOUT.

(S. ALLSOPP AND SONS, BURTON-ON-TRENT.)

That a large firm of brewers should add to their business that of brewing light beer on the continental, or what is known as the low fermentation, system may be taken to indicate an increasing demand on the part of the English public for lighter malt liquors. Allsopp's lager beer shows pretty much the same composition as the light beers brewed in Germany and elsewhere. Our analysis was as follows: alcohol, by weight 3·41 per cent., by volume 4·28 per cent., equal to proof spirit 7·49 per cent.; extractives, 4·45 per cent.; mineral matter, 0·17 per cent.; sugar, 0·74 per cent.; and volatile acidity reckoned as acetic acid, 0·078 per cent. It is thus a light, sound, clean beer with low alcoholic strength. It is agreeably and delicately bitter to the taste, but of course it should be kept cool and drunk cold, otherwise the peculiarly attractive flavour of beer brewed with bottom yeast is lost. The stout gave the following results on analysis: alcohol, by weight 6·71 per cent., by volume 8·36 per cent., equal to proof spirit 14·66 per cent.; extractives, 6·67 per cent.; mineral matter, 0·33 per cent.; sugar, 0·357 per cent.; proteid, 0·52 per cent.; and volatile acidity reckoned as acetic acid, 0·024 per cent. The stout was in excellent condition, free from an excess of carbonic acid gas and from the slightest sourness. The flavour was soft and decidedly malty. The stout answers the description of a malt liquor which is least likely to disturb digestion, since investigation has shown that acidity in beer and a large excess of gas are apt to have a retarding effect on digestion and to give rise to an acid condition of the contents of the stomach.

ROBORAT.

(THE ROBORAT CO., 27A, ST. MARY-AT-HILL, LONDON, E.C.)

The principal constituent of roborat, it is said, is pure unaltered vegetable albumin obtained from the seeds of cereals. It is a fine dry powder with a colour resembling oatmeal. It has the peculiar property of swelling up in water which is the characteristic behaviour of fresh albumin and at the same time a frothy liquid is obtained on shaking just as when egg albumin is similarly treated. Our analysis gave the following results: albumins, 79·02 per cent.; carbohydrate, chiefly starch, 5·78 per cent.; oil, including lecithin, 4·80 per cent.; mineral matter, 2·00 per cent.; and moisture, 8·40 per cent. Cold water extracted 6 per cent. of the powder, the extract consisting chiefly of soluble albumins. Alcohol and ether readily extracted lecithin. The mineral matter contained chiefly the phosphates of the alkaline earths. Roborat appears to be of decided value in the dietary of invalids. It is, of course, a powerful tissue-former, the albumins which it contains being readily digestible according to experiments made *in vitro*. In addition it contains an important proportion of lecithin which, as is well known, has a favourable influence on nutrition.

THE SALE OF POISONS AND DRUGS.—An official report on Indian legislation in 1904 mentions that an Act passed by the council of the Governor-General provided for the control of the sale of poisons generally within municipalities and cantonments, authorised the prohibition of the importation of white arsenic into British India except under licence, and empowered local governments to regulate the sale of that poison. The Act also took powers for the Governor-General in council to apply to any other poisons the provisions relating to white arsenic. Protection was secured for acts done in good faith by medical men, druggists, and others. The Legislative Council of Burma passed an Act enabling the Local Government to make, by proclamation, additions to the list of intoxicating drugs of which the sale and possession may be restricted under the provisions of the Excise Act, 1896. The circumstances which led to this legislation were the large increase in the sale of cocaine in Rangoon and the noxious results found to be attendant on the use of the drug.

The old-fashioned virtue of early rising may be insidiously undermined, it would seem, and slothful habits induced. Perhaps it is difficult in all cases to hit the golden mean and conflicting theories take time to adjust themselves in practice. Still there is no reason why sanitary houses, proper food, and adequate sleep should have anything but a good influence upon the rising generation of young Englishmen. The tendency to spare the rod is probably carried too far in deference to false sentiment and ignorant outcry, but we do not wish to bring back the "good old" days of fighting and bullying, of semi-starvation, dirt, and cold. These may have been potent means of natural selection in their day but times are changed and other qualities are demanded than mere muscle, animal spirits, and aggressiveness. There is no evidence that the products of our public schools have less average capacity for work in the world than those of past generations, though statements to the contrary are often made. Outstanding examples may be fewer just because the general level has been raised rather than lowered, but we fancy that the total production of good is increased. At any rate, wisdom seems to lie in removing visible obstacles to physical health so far as can be done and counteracting any tendency to resulting softness, should such really exist, by other means than conditions of barbarism. Dr. ACLAND's paper will, we hope, have the excellent result of convincing some of our scholastic authorities that a growing boy is more hungry for sleep even than for food.

Medical Students' Early Years.

THE problem of how best to regulate the early years of medical student life in London is not the least of the difficulties created by the embarrassed financial position of metropolitan hospitals and their affiliated schools. It is an educational problem of the greatest interest and importance, not only to those particularly concerned with medical education but also to the public at large. As the medical student is, so to a large extent will be the medical practitioner, and it concerns us all that the management of medical education shall tend to create from a body of high-spirited and well-informed young men a body of sensible, honest, and industrious practitioners. The needs of the exceptional student we may put on one side. It is the average young man whom we have to consider and how the highest average standard of general and of medical excellence is to be obtained. We say general excellence advisedly, for although the medical school, strictly speaking, offers nothing but medical education, yet actually each school prides itself not only on the proficiency which it offers to its members in the various branches of medical science and art but also on the spirit with which tradition and a continuous series of enthusiastic physicians and surgeons have furnished it. To impart the desirable qualities of keenness, of good sense, of responsibility, and of laudable ambition there can be no regulated system of instruction. They spring from the atmosphere of a hospital and from the imitation of fine examples. There are, and can be, no classes in manners, in kindness, and in the proper way to talk to patients. It is none the less an essential part of the medical student's education that he shall be able to watch these qualities in others and to acquire them for himself. His teachers and his surroundings, in a word, must make him not merely a competent practitioner but also an estimable man.

As many of our readers are doubtless aware, a changed arrangement of the student's preliminary years is coming about in London. A concentration of the teaching of preliminary subjects will be effected, and this is, in our opinion, desirable. Moreover, so far as some of the schools are concerned it is imperative, having regard to the curtailment of the financial help which a hospital can grant to its school. Will this scheme of amalgamation, when it has taken shape, influence in any way unfavourably the desirable effects of hospital life? We think that it will not, but we know that this view is not shared by some hospital authorities who see in the removal of the student at the beginning of his career from the influences of a hospital school a considerable source of danger. We believe that these fears are ill-founded. It must be remembered that the medical student is no longer a schoolboy, nor is he in many instances even in the same relation to his hospital that the undergraduate of Oxford or of Cambridge is to his college. A considerable proportion of the medical students in London have, in fact, passed through their undergraduate stage at Oxford or Cambridge or some other university. Yet amongst these very men, the men who have passed through perhaps their most impressionable days before they ever entered hospital, are to be found supporters as keen, as loyal, and as devoted of the hospitals to which they have attached themselves as amongst any other class of student whatsoever. It is probable that all the good influences which a hospital can exert, and these are many and real, can be, and are, as well and as successfully brought to bear upon the third-year man as upon the student who begins as well as finishes his education on the premises of a London hospital. Is it rational to suppose then that because in the future this student will have studied physics and chemistry, anatomy and physiology at the University of London, therefore when he goes through his clinical education at a metropolitan hospital, the good influences and traditions with which that hospital has enveloped so many generations of students will have an effect that is unavailing or diminished in his case?

The effects upon conduct and upon character that are wrought by the student's life within the walls of a hospital arise mostly from the nature of the work and from its tendency to make him take a thoughtful and a sympathetic view of human affairs, both bodily and spiritual. It is an effect that will be produced upon impressionable minds, a seed which will grow in the proper soil, whether it is planted to some extent from the earliest years of a medical student's life or whether, on the other hand, it is withheld until his entry into the wards only to be sown then in a fuller abundance. Moreover, it will be the duty of hospital authorities to see that the student reaps even during his preliminary years such benefits as a sense of comradeship and of belonging to an honourable institution can confer upon him. He will have joined the ranks of a hospital before his work takes him habitually to the building, and when the time comes for him to be there as dresser and as resident we have no fears that the *régime* of

The Sleeping Hours of Schoolboys.

In the present strenuous age of hurry and bustle there is a tendency to begrudge an expenditure of time upon such apparently unprofitable things as rest and recuperation, and for the busy man as well as for the pleasure-seeker the hours devoted to sleep are cut down to the irreducible minimum. We have heard of a society in America the members of which bound themselves to curtail more and more the period of slumber till most of them managed to do with only four or five hours in the 24. It was never recorded, so far as we know, what was the average life of these poor victims. Our ancestors had an adage that six hours' sleep was the proper quantity for a man, seven for a woman, and eight for a fool. Whether it is that the strenuous life of the present day is akin to foolishness or whether it is a simple phenomenon of evolution, it is certain that many of our busiest men find the last-mentioned allowance none too long for them. The quality of a man's work soon deteriorates if he takes insufficient rest and a regard for real as contrasted with apparent profits should compel attention to considerations of health. But if sleep is requisite for the adult, how much more so is it indispensable for growing children? Rapid growth and the abundant energy characteristic of the young imply rapid multiplication of cells and renovation of tissue, and sleep is the time for both growth and repair. Yet it is a feature of child life to which our educational authorities seem to have paid but little attention. Here, as in other educational matters, America is ahead of us, much more adequate periods of rest being allowed in the schools in the United States than in this country. Dr. T. D. Acland has done good service in calling attention to the subject in his paper read before the Medical Officers of Schools' Association, which appears at p. 136 of our present issue. He has collected a mass of weighty opinions which should carry conviction to his hearers and readers. It is, perhaps, not very easy to lay down definite rules which shall apply to all children even at the same age, since individuals differ in this as in other respects. But there seems to be a striking agreement among medical and scientific writers that at present we err on the side of deficient allowance of sleep.

Schoolboys may be roughly divided into those of public school age and those still in the preparatory stage, the latter being between the ages of nine and 13 and the former from 12 to 18 years. For little boys who have just left home for the first time ten hours of sleep are probably none too much, and this amount would be obtained pretty accurately by insisting upon their going to bed at 9.30 and having breakfast at 8. The elder boys still at a private school might be allowed to sit up until 10 o'clock. At public schools 10 p.m. is probably the usual, and certainly a convenient, time for bed, and only the upper forms should be allowed to postpone the time of "lights out" to any later hour. Breakfast could here be at 7.30 without undue stress of work. Of course it must be recognised that all the time between the hour of going to bed and that of breakfasting is not spent in actual sleep, so that in order to secure as much sleep as possible it is necessary, at all events with younger boys who occupy dormitories in common, to prevent talking and "skylarking" going on when the lights are out. It is also advisable to arrange that younger and older boys do not share the same sleeping rooms, lest the little ones, who go to bed early, may be disturbed by the subsequent entrance of the seniors. Very closely connected with the question of sufficient sleep is that of lessons before breakfast, and we are strongly of opinion that it is wrong on physiological grounds to expect boys to start brain-work in the early morning on empty stomachs. Breakfast should be the first event of the day and should be followed by a short interval, for obvious reasons, before assembly in the class-rooms. One of the most important features of education is the inculcation of good habits which soon become a second nature. Sleep indeed itself, as pointed out by Dr. T. B. Hyslop, is to some degree a matter of habit, but it is doubtful how far it is one which need be much impressed upon children who seldom sleep badly unless they are definitely ill or overworked. The occurrence of sleeplessness in them is always a symptom which needs careful attention as it may afford a danger signal pointing to the onset of nervous maladies or to the existence of over-pressure in school work. It may seem curious that so late in the history of the world as the beginning of the twentieth century it is necessary to insist upon the allowance of proper time for sleep, but the fact may be readily explained. On the one hand, the old and not yet obsolete theory of education as a means of stocking boys' memories with as large as possible a number of facts and endowing them with certain fashionable accomplishments rather than as training the minds of the young in such a way that they may best adapt themselves to the circumstances of after life, has led to the multiplication of hours of instruction, to the neglect in many instances of the laws of health. On the other hand, it is only in recent years that these laws have been recognised by the general public with anything like intelligent appreciation, and the traditions of school life are guarded with a curiously jealous conservatism which renders change of any kind specially difficult to carry out. Hence, some of our great schools are in certain respects behind the times in their health arrangements, while parents are often sadly ignorant of all that pertains to the upbringing of children.

There are signs that the schools, especially the English public schools, are becoming awake to their shortcomings and are setting their houses in order. The chief opposition now comes from those who see in all attempts to make life at school more healthy a proof of yielding to the softer, not to say more effeminate, spirit of modern times. This cry is raised even over the question of longer hours for sleep, as Dr. Acland points out.

of 1904:[3] "The diffusion of a general knowledge of the way to live amongst the poorer classes of the population will, we think, prove the charter of the people's physical salvation and it should, too, tend after some years to make the differences between the infantile mortality of the upper and the lower classes less pronounced than is the case at the present time." The medical profession has always been active in promoting all movements tending to the improvement of the public health and the general well-being of the people and we feel sure that the new league will receive the hearty support and active coöperation of all practitioners of medicine. After all, it is public interest in these matters which must be awakened if practical results are to be achieved and it is this which the league hopes to effect. Without such general public support legislation is likely to be delayed and the evils to remain; with it we may hope for the ideal which Sir LAUDER BRUNTON held forward in his speech supporting the foundation of the league at the Mansion House, that we should have "every man, woman, and child better fed, stronger, and better educated, and with a better morality following on a better physique."

Annotations.

"Ne quid nimis."

PREGNANCY LATE IN LIFE.

THE fact that a woman may become pregnant quite late in life has long been recognised by writers on obstetric medicine; when, however, many of the so-called authentic cases are subjected to a critical examination the worthlessness of most of them soon becomes apparent. While cases have been recorded by trustworthy observers of women of 60 years or so who have borne children we must regard with much suspicion the accounts of the occurrence of pregnancy at the extraordinary age of 70 years, as in a case recorded by Haller, or the cases mentioned by Gould where the mother was respectively 73, 90, and 103 years of age. In St. Peter's Church in Oxford there is a monument bearing an inscription recording the death in childbed of a woman 62 years old. The late Dr. Fordyce Barker collected a number of these cases and met with an interesting instance in his own experience in which a woman 58 years old claimed to have given birth to a child. The death of the infant, shortly followed by the death of the mother, diverted the descent of a large property which she had inherited and gave rise to a law-suit which established the fact that the woman had not been pregnant at all but had borrowed the child for the occasion. The chances of a woman bearing children when over the age of 50 years are decidedly small and they are, of course, still less when the menopause has ensued. Of 51,229 births taking place in Berlin in the year 1898, 138, or 0·371 per cent., of the mothers were between 45 and 50 years of age, and only four, or 0·007 per cent., were over 50 years. One of the most remarkable cases of pregnancy at an advanced period of life is that recorded by Kennedy. He delivered a patient in her twenty-third pregnancy at the age of 62 years. The labour was spontaneous and the child, a healthy male, was born alive. The patient had had 21 children at full term, the last seven pregnancies occurring after the forty-seventh year and the last but one ending in a miscarriage at the age of 60 years. Menstruation had been regular up to the commencement of the last pregnancy. In Meissner's case the woman began to menstruate at the age of 20, she had her first child at the age of 47, and the seventh and last at the age of 60 years. Her periods then ceased but returned and were regular from the seventy-fifth to the ninety-eighth year; then they ceased again for five years and returned in the 104th year. Unfortunately the patient was then lost sight of. Capuron records a case of abortion at the third month in a woman 66 years old. It is, of course, not surprising to find a patient who is still menstruating becoming pregnant, even although she may be of an advanced age, but such an occurrence is much more extraordinary when the patient has ceased to menstruate. Cases, however, even of this kind have been described and the observations of Leopold and others have shown that ova may mature both before puberty and after the menopause. A further proof that the presence of menstruation is not necessary in order that impregnation may take place is afforded by the cases in which pregnancy commences during prolonged periods of amenorrhœa, and the occurrence of such cases of pregnancy shows that the discharge of ova takes place in these conditions. One of the most interesting cases of repeated pregnancies with absence of the menstrual periods is that recorded by Strassmann. The patient, a woman 45 years of age, commenced to menstruate at 16 years. The periods continued regularly until the eighteenth year when she had her first baby. From the eighteenth to the thirty-ninth year she did not menstruate at all and during this time she had 17 full-term pregnancies and a three months' miscarriage. At the age of 39 years menstruation returned and continued at regular monthly intervals until the age of 45 years. It is difficult to form an accurate estimate of the possibility of a woman becoming pregnant who has ceased to menstruate from the occurrence of the menopause. We have seen that even when the periods are still present at an advanced age the percentage of women in whom pregnancy occurs is relatively small and the chances against its occurrence are very large. A certain number of cases, however, are on record where, after the complete cessation of the periods, pregnancy has taken place. Their total number is, however, but a small one, especially if we eliminate all those in which there has been a return of the periods after the pregnancy. For example, in a case recorded by Priou the patient had her last child at the age of 48 years. She suckled the child and saw no catamenia afterwards. 24 years later, at the age of 72, she menstruated regularly for a period of six months, the menses then ceased for eight weeks, and she had a two months' miscarriage. Underhill and Lavasseur have met with cases in which the patients, at the ages of 49 and 50 years respectively, gave birth to children, in each instance after the periods had ceased for the space of two years. A still more striking case is that related by Depasse of a woman who ceased to menstrate at 50 years and had a baby at the age of 59 years, which she weaned on her sixtieth birthday. Hann has also met with a case in which three years after the menopause a patient became pregnant, but in this instance the periods returned regularly after the birth of the child and, as we have pointed out, such cases are not quite on the same footing as those in which the periods are never seen again.

MEDICAL EXCURSIONS FOR STUDENTS OF MEDICINE.

SOME three years ago M. Etienne Bazot organised a system of "Voyages Médicaux" which was intended to give medical men and others interested in science the opportunity of visiting French places which possessed a medical or other scientific interest, and if the "voyages" were properly appreciated of extending them to other countries. M. Bazot the future will not afford him that opportunity for a sound development both of knowledge and of manly character which the London hospitals have so notably provided hitherto.

◆

The Proposed National League for Physical Education and Improvement.

DURING the two and a half years which have elapsed since the publication of Major-General Sir FREDERICK MAURICE'S article in the *Contemporary Review* under the title of "National Health: A Soldier's Study," drawing attention to the deficient physique of youths presenting themselves for enlistment as recruits to the British army, few subjects have achieved a larger meed of attention than that of the supposed physical deterioration of our countrymen. In commenting on Sir FREDERICK MAURICE'S article[1] we ventured to doubt the soundness of his conclusions and to be sceptical of the existence of any progressive physical deterioration, in which we were confirmed by the report of the Inter-departmental Committee appointed to consider the question. The general conclusion of the committee was that "the impressions gained from the great majority of the witnesses examined do not support the belief that there is any general progressive physical deterioration." On the other hand, the investigations of the committee, while tending to allay anxiety in this direction, have shown that in matters of national health and physical well-being all is not well with us, and in its conclusions the committee offers some fifty suggestions for dealing with some of the more important evils, such as overcrowding, excessive infantile mortality, and the progressive urbanisation of the population. No better testimony to the value of these recommendations of the Inter-departmental Committee could be adduced than the number of movements which have been started recently by influential groups of philanthropic, scientific, and public-spirited men and women to arouse public interest with a view to insure legislative and municipal action to give effect to them.

In April of this year a meeting was held in London at the Examination Hall, Victoria Embankment, under the presidency of Sir WILLIAM H. BROADBENT, to promote the teaching of hygiene and temperance in elementary schools, to which we referred in a leading article.[2] A deputation subsequently waited upon Lord LONDONDERRY, the Lord President of the Council, to urge the importance of this matter. Again, in the *Times* of June 29th there was a note concerning the presentation of a memorial to Lord LONDONDERRY by the Anthropological Institute, and signed by others not belonging to the institute, praying that an anthropometric survey, a register of sickness, and an advisory committee to advise the Government on all legislative and administrative points concerning the public health might be established without delay, as recommended by the Inter-departmental Committee. It is difficult to over-estimate the benefits likely to accrue if these proposals are effectively carried out, and all medical practitioners will welcome the valuable information concerning anthropometric data and the increased knowledge of the incidence of disease and variation in type which are likely to ensue. The most recent movement has resulted in the formation of a league the actual title of which is not yet settled. The inaugural meeting was held at the Mansion House on June 28th under the presidency of the LORD MAYOR, but the movement has been in progress for some time and owes its inception largely to the energy and public spirit of the Bishop of RIPON, Sir LAUDER BRUNTON, and Sir HENRY CRAIK. The main objects of the league are to arouse public interest in matters relating to the physical condition of the people generally throughout the country; to correlate and to bring into association the various agencies at present at work to diffuse knowledge of the rules of health and of domestic hygiene; to endeavour to improve the physique of the rising generation; and to form organisations for these purposes where they do not exist. The movement is, moreover, national in character, non-sectarian, and non-political, and has the support of a large number of influential men. A draft scheme of the new league has been published in which it is suggested that there should be a central administrative organisation with local branches throughout the country. Each branch is to encourage all agencies in its own district which have for their object the promotion of physical well-being, to instruct mothers in the feeding and care of their children, to see that adequate opportunities are available for open-air games and physical exercises for both boys and girls, and, in fact, to foster all efforts to improve the general health and physique of the people.

The Inter-departmental Committee insisted on the importance of promoting measures to combat that perennial source of national disquietude, the excessive infantile death-rate, which is so great that in some of the most crowded districts of London it is as high as 223 per 1000—figures which are the more disquieting when we take into consideration the fact that at present stillbirths are not registered and therefore are not included in these figures That this appallingly high mortality is due in no small measure to ignorance on the part of the mothers of the elementary rules of infant feeding and nurture few can doubt who have experience of the homes of the poor or of out-patient departments at children's hospitals. The new league will achieve a work of truly national importance if it can bring about a general diffusion of these elementary rules by skilled, tactful, and specially educated district visitors or inspectors, as is now being done in a few of the more advanced municipalities. To insist on the importance of breast-feeding of infants wherever possible, to insure the purity of the milk-supply, and to instruct the mothers in the modification and use of cow's milk for purposes of infant feeding where necessary as a substitute for breast-milk are matters of vital importance. There is nothing new or original in these recommendations which have been urged again and again, but the time would now seem to be ripe for action, and with public interest awakened in the matter the league may be able to secure legislative measures to give effect to these urgently needed reforms. We have frequently insisted on the great importance of these matters and we may quote the following paragraph from the Annus Medicus glands and spleen. There were a large number of lymphoid cells, of large phagocytes, and at the same time a condition of hyperplasia of the blood-forming cells. There were also usually disseminated foci of necrosis and in patients dying from perforation peritonitis, diffuse degenerative changes, with marked congestion and œdema. Differential counts of the marrow cells in ten of the cases showed a marked relative increase in the non-granular or lymphoid variety of cell over the granular myelocytes. A different condition was found in the cases of acute pneumonia, of acute peritonitis, of cerebro-spinal meningitis, of puerperal septicæmia, and of retro-peritoneal abscess, in all of which there was a marked relative increase of the granular myelocytes over the non-granular cells. Moreover, no foci of necrosis were found and large phagocytic cells were rare or entirely absent. In the cases of chronic nephritis and of carcinoma of the gall-bladder there were no distinctive pathological changes and the conditions closely approximated to those in the two normal cases. Dr. Longcope discusses the significance of his observations and the probable manner in which the typhoid toxins produce these changes.

A CENTURY OF EMPIRE: ITS LESSONS AND RESPONSIBILITIES.

THE *Fortnightly Review* last month contained an article by Major-General Sir Thomas Fraser, K.C.B., on "A Century of Empire," to which we may call the attention of our readers because it deals in an able and a comprehensive manner with the subject treated. The author describes in a brief but realistic way the great growth of the British Empire that has taken place during the past century. He inculcates the necessity which exists for us as the leading race "to think imperially" and to realise a sense of unity or unification of purpose by being prepared to take a full personal share in the burthen of war if the scattered fragments composing that empire are to be maintained and held together in the future. Like all stories worth the telling, the moral of what General Fraser has to say lies on the surface. The principle that it is the duty of every citizen to qualify himself by an acquaintance with some form or other of army drill and military formations and with the use of the rifle in order to take his part if need be in the defence of his country seems to us to be sound and justifiable, and, what is more, we believe that if this principle were acted on it would for hygienic and disciplinary reasons lead to the physical and moral improvement of all concerned. In common with many other people it fell to our lot to study several of the numerous reports and articles which appeared during, and since the termination of, the war in South Africa and subsequently to read much in connexion with the momentous and dramatic series of events which have been taking place in the great struggle for supremacy in the Far East. The full force and effect, however, of what has been accomplished during the present war we have yet to learn. It is needless to say that these illustrations of modern warfare conducted on new principles and on a colossal scale have compelled attention to such questions as the organisation of our own forces for effectual national and imperial defence. Notwithstanding the reports and recommendations of Royal Commissions, the strenuous efforts of War Ministers, and the official and non-official suggestions of all sorts and conditions of men it cannot be said that a scheme has yet been devised which commands any general feeling of confidence and hearty assent. Such a measure must be not only so comprehensive in its nature and scope as to be capable of fulfilling the requirements of the empire but it must at the same time be of such a character also as to be suitable, practicable, and reasonably adaptable to the present time and circumstances. Is it beyond the power of our statesmen to design some rational scheme for compulsory national training in order to avoid compulsory service, which is a different thing? We cannot think so, difficult as the task is; neither do we think that our various colonies and dependencies would refuse to aid and to coöperate in giving effect to any bold and well-considered measure for imperial defence. Nor should the fact be lost sight of that the sanitary and medical requirements of armies of the present day have also to be taken into account in considering any big scheme of this kind, the settlement of which, whatever may be said or thought to the contrary, is one of the vital questions of the present time.

MYELOGENOUS LEUKÆMIA WITH MULTIPLE TUMOURS OF THE SMALL INTESTINE.

AT the meeting of the Société Médicale des Hôpitaux of Paris on June 23rd M. Maurice Letulle and M. Paul Halbron described the following remarkable case. A married woman, aged 25 years, was admitted into hospital on Jan. 25th, 1904, complaining of digestive troubles. She had a daughter, aged five years, who was in good health. The patient had not suffered from any previous illness except the ordinary maladies of childhood. She said that two months before admission she became ill with bronchitis and that digestive troubles followed. She vomited after meals and once had hæmatemesis. Then she noticed a large mass in the left flank. On admission she was pale and emaciated but not cachectic. There were strumous scars in the neck. In the left hypochondrium and left flank was a large and slightly tender tumour which descended almost as low as the pubes. It was slightly moveable and was evidently the spleen, though no notch could be felt. Examination of the blood showed that the patient was suffering from myelogenous leukæmia but she would not remain in hospital. She was readmitted in July in an extremely feeble and cachectic state. The abdomen was distended and gave the sensation of fluctuation. There was dyspnœa so great that paracentesis abdominis had to be performed immediately. About 17 pints of pale green slightly lactescent fluid were removed and the patient was greatly relieved. On the following day the fluid was again beginning to collect. The enlarged spleen could be felt and did not appear to be as big as it was in January. Thick, hard, and irregular masses were felt in the abdomen, which seemed like those due to tuberculous peritonitis. Death took place on this day. An examination of the blood made in the morning showed 2,150,400 red and 482,680 white corpuscles per cubic millimetre. A differential count of the latter gave the following percentages: polynuclear neutrophiles, 38·4; polynuclear eosinophiles, 3·6; polynuclear basophiles, 4·0; neutrophile myelocytes, 30·4; eosinophile myelocytes, 8·0; basophile myelocytes, 4·0; lymphocytes, 1·2; large mononuclears, 6·0; and transitional forms, 4·4. No nucleated red corpuscles were found. The deposit formed by centifugalisation of the ascitic fluid contained numerous polynuclears, a large number of myelocytes, mononuclears, endothelial cells, and many red corpuscles, of which a few were nucleated. At the necropsy a large quantity of hæmorrhagic fluid was found in the peritoneal cavity and the pelvis contained almost pure blood. Two kinds of lesions were observed on the coils of small intestine—(1) patches of arborescent vessels accompanied by recent false membrane; and (2) projections constituting veritable tumours of varying size. The largest were of the size of a mandarin orange. The tumours were smooth, soft, and elastic. The overlying peritoneum was normal. On the mesentery were similar masses. Tumours of a different kind were also present and the coils of intestine which bore them looked like shagreen. These tumours formed large dome-like papules. The mucous membrane of the was struck by the success of the visit of French medical men to our shores last year and of the return visit by British medical men to France during this year, and his organisation now proposes that a somewhat similar visit shall be paid to France by British students of medicine and "internes"—i.e., house physicians and house surgeons. The tours are not, of course, intended to be, as were the visits of the French and British medical men, purely complimentary, but have been drawn up after the manner of the well-known excursions to French watering-places conducted by Dr. Landouzy. Four tours have been arranged for, one lasting 20 days and costing 455 francs including everything, a les expensive one lasting 15 days and costing 375 francs, one lasting 12 days and costing 275 francs, and finally one lasting seven days and costing 180 francs. It is proposed that these tours should take place in August when the French students will be at liberty to receive their British *confrères* and it is hoped that next year a return visit will be paid to this country by French students. Any further information will be supplied by M. E. Bazot, Administrateur des Voyages Médicaux au Service Annexe de l'Œuvre, 1, Rue de l'Echelle, Paris. We are afraid, however, that the scheme has been laid before us too late for anything to be done this year, the medical schools having broken up for the vacation. We are all the more sorry that this should be so, for the idea seems to us to be a very good one and the programme arranged is certainly attractive. For instance, that for the 12-day tour at 275 francs includes a visit to Calais, Lille, Paris, Vichy, Royat, La Bourboule, Mont Dore, Néris-les-Bains, Boutges, and back by Paris to London. Concerts, receptions, theatres, and other entertainments have been arranged for and no one, we think, would regret going.

THE DIRTY DOOR HANDLE.

A DIRTY door handle is an obvious offence against sanitary principles. From a strictly bacteriological point of view all door handles, even those which present a clean and polished appearance, are probably dirty. Constant contact with the hand means contamination sooner or later and the kind and degree of contamination depend, of course, upon the conditions to which the hand has been exposed. It is conceivable that a dirty door handle would convey disease and there is thus ample reason why door handles should be kept as clean as possible. If this cannot be done the institution of the door handle should be abolished in favour of some method which dispenses with actual contact of the skin There is much to be said in favour of a foot lever for opening doors, as there is in the case of a foot lever instead of taps in the lavatory, but perhaps there might be difficulties in the application of this to railway carriages. Every railway passenger has experienced to his intense annoyance the unspeakable griminess of the door handle of a carriage, say, on the Underground Railway or any other railway the track of which lies through smoky tunnels. It avails little to polish these handles occasionally for they are so soon begrimed again. At one time there was no such thing as an inner handle communicating with the outer handle and so the passenger who wanted to get out had to soil his hands unless an obliging porter happened to be near. But the inside handle is clearly no remedy for the passenger who wants to enter a train. The undoubted evil of dirty door handles on the railway carriage is practically abolished on corridor trains in which, as on the tube railways, the duty of opening and closing the doors devolves entirely upon the conductor. It will probably be a long time, however, before the single compartment system is done away with, and as long as it exists so also will the ever-occurring nuisance of the dirty door handle. Some attempts apparently have been made to mitigate the evil, for we know of at least one railway company which, at any rate in some of its carriages, has adopted a short handle to turn which requires only a small effort owing to the operation of a lever inside the lock. Indeed, the lock may be easily released by a slight pressure of the thumb and the forefinger and only a slight soiling of the fingers is involved. Most railway carriage door handles, however, are large and clumsy, requiring a complete grip with the whole hand before any effect upon the lock can be obtained. In such a case the fouling of the hand is complete. Surely such a disagreeable system of opening the doors of railway carriages could be replaced by some much less objectionable method. Dirt is, of course, largely inseparable from the railway train but we think that this particular and offensive evidence of it might easily be minimised. At all events, no contrivance for the purpose could be better adapted to soil the hands of the passenger than the handles in use at the present time by most of our railway companies.

THE BONE MARROW IN TYPHOID FEVER.

THE characters of the leucopenia or hypoleucocytosis of typhoid fever have been carefully studied, notably by Naegeli and Thayer. The most characteristic changes in the leucocyte count of an uncomplicated case are a decrease in the number of polymorphonuclear leucocytes and a relative increase in the number of lymphocytes, especially of the hyaline or large lymphocyte variety, while the eosinophiles are diminished or absent. This leucopenia is as a rule well marked during the second week and persists into the period of convalescence. When complications arise, especially such as are due to secondary infection, varying degrees of leucocytosis occur with an increase in the number of polymorphonuclears, though often to a less degree than would be produced by a similar infection if occurring primarily. This point has recently been emphasised by Kast and Gutig, who after a study of 40 cases of typhoid fever complicated by secondary infections found that in 80 per cent. of them the leucocyte count ranged below 7000 per cubic millimetre. This was especially so in cases of perforation of a typhoid ulcer followed by general peritonitis. It is obvious that a study of the condition of the bone marrow in cases of typhoid fever is of great interest in this connexion but few observations are recorded bearing upon this matter. Fraenkel has drawn attention to focal necrosis of the bone marrow in some cases and Mallory has described changes in the bone marrow similar to those occurring in the spleen. The subject has been investigated in a laborious and painstaking research by Dr. Warfield T. Longcope, whose conclusions are recorded in an interesting paper published in the Proceedings of the Pathological Society of Philadelphia (Vol. VIII., No. 2, p. 49, 1905), to which is appended a useful bibliography. The condition of the bone marrow was investigated in 26 cases of typhoid fever, and for purposes of comparison in 15 cases of pneumonia, two of miliary tuberculosis, one of acute cerebro-spinal meningitis, one of retroperitoneal abscess, one of puerperal septicæmia, four of chronic nephritis, one of carcinoma of the gall-bladder, and also in two normal individuals (in the leg immediately after amputation for accident). Details are given of the methods used and of the conditions observed. Dr. Longcope divides the cells of the marrow into two groups, the first being the granular cells, and comprising the neutrophilic granular myelocyte and the eosinophilic granular myelocyte together with the ordinary polymorphonuclear leucocyte and the eosinophiles. The second group, that of the non-granular cells, includes the large and small lymphocytes. The 26 cases of typhoid fever showed definite and fairly constant changes which closely resembled those found in the mesenteric lymph *glands and spleen.* There were a large number of lymphoid cells, of large phagocytes, and at the same time a condition of hyperplasia of the blood-forming cells. There were also usually disseminated foci of necrosis and in patients dying from perforation peritonitis, diffuse degenerative changes, with marked congestion and œdema. *Differential counts* of the marrow cells in ten of the cases showed a marked relative increase in the non-granular or lymphoid variety of cell over the granular myelocytes. A different condition was found in the cases of acute pneumonia, of acute peritonitis, of cerebrospinal meningitis, of puerperal septicæmia, and of retroperitoneal abscess, in all of which there was a marked relative increase of the granular myelocytes over the non-granular cells. Moreover, no foci of necrosis were found and large phagocytic cells were rare or entirely absent. In the cases of chronic nephritis and of carcinoma of the gall-bladder there were no distinctive pathological changes and the conditions closely approximated to those in the two normal cases. Dr. Longcope discusses the significance of his observations and the probable manner in which the typhoid toxins produce these changes.

A CENTURY OF EMPIRE: ITS LESSONS AND RESPONSIBILITIES.

THE *Fortnightly Review* last month contained an article by Major-General Sir Thomas Fraser, K.C.B., on "A Century of Empire," to which we may call the attention of our readers because it deals in an able and a comprehensive manner with the subject treated. The author describes in a brief but realistic way the great growth of the British Empire that has taken place during the past century. He inculcates the necessity which exists for us as the leading race "to think imperially" and to realise a sense of unity or unification of purpose by being prepared to take a full personal share in the burthen of war if the scattered fragments composing that empire are to be maintained and held together in the future. Like all stories worth the telling, the moral of what General Fraser has to say lies on the surface. The principle that it is the duty of every citizen to qualify himself by an acquaintance with some form or other of army drill and military formations and with the use of the rifle in order to take his part if need be in the defence of his country seems to us to be sound and justifiable, and, what is more, we believe that if this principle were acted on it would for hygienic and disciplinary reasons lead to the physical and moral improvement of all concerned. In common with many other people it fell to our lot to study several of the numerous reports and articles which appeared during, and since the termination of, the war in South Africa and subsequently to read much in connexion with the momentous and dramatic series of events which have been taking place in the great struggle for supremacy in the Far East. The full force and effect, however, of what has been accomplished during the present war we have yet to learn. It is needless to say that these illustrations of modern warfare conducted on new principles and on a colossal scale have compelled attention to such questions as the organisation of our own forces for effectual national and imperial defence. Notwithstanding the reports and recommendations of Royal Commissions, the strenuous efforts of War Ministers, and the official and non-official suggestions of all sorts and conditions of men it cannot be said that a scheme has yet been devised which commands any general feeling of confidence and hearty assent. Such a measure must be not only so comprehensive in its nature and scope as to be capable of fulfilling the requirements of the empire but it must at the same time be of such a character also as to be suitable, practicable, and reasonably adaptable to the present time and circumstances. Is it beyond the power of our statesmen to design some rational scheme for compulsory national training in order to avoid compulsory service, which is a different thing? We cannot think so, difficult as the task is; neither do we think that our various colonies and dependencies would refuse to aid and to coöperate in giving effect to any bold and well-considered measure for imperial defence. Nor should the fact be lost sight of that the sanitary and medical requirements of armies of the present day have also to be taken into account in considering any big scheme of this kind, the settlement of which, whatever may be said or thought to the contrary, is one of the vital questions of the present time.

MYELOGENOUS LEUKÆMIA WITH MULTIPLE TUMOURS OF THE SMALL INTESTINE.

AT the meeting of the Société Médicale des Hôpitaux of Paris on June 23rd M. Maurice Letulle and M. Paul Halbron described the following remarkable case. A married woman, aged 25 years, was admitted into hospital on Jan. 25th, 1904, complaining of digestive troubles. She had a daughter, aged five years, who was in good health. The patient had not suffered from any previous illness except the ordinary maladies of childhood. She said that two months before admission she became ill with bronchitis and that digestive troubles followed. She vomited after meals and once had hæmatemesis. Then she noticed a large mass in the left flank. On admission she was pale and emaciated but not cachectic. There were strumous scars in the neck. In the left hypochondrium and left flank was a large and slightly tender tumour which descended almost as low as the pubes. It was slightly moveable and was evidently the spleen, though no notch could be felt. Examination of the blood showed that the patient was suffering from myelogenous leukæmia but she would not remain in hospital. She was readmitted in July in an extremely feeble and cachectic state. The abdomen was distended and gave the sensation of fluctuation. There was dyspnœa so great that paracentesis abdominis had to be performed immediately. About 17 pints of pale green slightly lactescent fluid were removed and the patient was greatly relieved. On the following day the fluid was again beginning to collect. The enlarged spleen could be felt and did not appear to be as big as it was in January. Thick, hard, and irregular masses were felt in the abdomen, which seemed like those due to tuberculous peritonitis. Death took place on this day. An examination of the blood made in the morning showed 2,150,400 red and 482,680 white corpuscles per cubic millimetre. A differential count of the latter gave the following percentages: polynuclear neutrophiles, 38·4; polynuclear eosinophiles, 3·6; polynuclear basophiles, 4·0; neutrophile myelocytes, 30·4; eosinophile myelocytes, 8·0; basophile myelocytes, 4·0; lymphocytes, 1·2; large mononuclears, 6·0; and transitional forms, 4·4. No nucleated red corpuscles were found. The deposit formed by centifugalisation of the ascitic fluid contained numerous polynuclears, a large number of myelocytes, mononuclears, endothelial cells, and many red corpuscles, of which a few were nucleated. At the necropsy a large quantity of hæmorrhagic fluid was found in the peritoneal cavity and the pelvis contained almost pure blood. Two kinds of lesions were observed on the coils of small intestine—(1) patches of arborescent vessels accompanied by recent false membrane; and (2) projections constituting veritable tumours of varying size. The largest were of the size of a mandarin orange. The tumours were smooth, soft, and elastic. The overlying peritoneum was normal. On the mesentery were similar masses. Tumours of a different kind were also present and the coils of intestine which bore them looked like shagreen. These tumours formed large dome-like papules. The mucous membrane of the intestine was normal. The mesenteric glands were a little swollen. The spleen weighed 1620 grammes; it was firm, hard to the knife, and on section showed a homogeneous surface of the colour of normal muscle. The liver weighed 1675 grammes and had a normal appearance except that it looked a little pale and that in places there seemed to be small hæmorrhages. The bone marrow appeared to be normal. Microscopic examination showed that the subserous coat of the intestine was considerably hypertrophied, its thickness exceeding a centimetre. It was traversed by numerous vessels of new formation. Around these were developed connective-tissue fibres, in the meshes of which were polynuclear cells, principally neutrophiles, myelocytes, and lymphocytes. There were also giant cells which invaded the muscular coat. On the peritoneal surface were dense, non-vascular, false membranes, full of lymphocytes and polynuclear cells. The tumours were composed of the same tissue as that which produced the diffuse hypertrophy of the submucous coat. In the meshes of the connective tissue were some liquid, numerous neutro-, baso-, and acidophile myelocytes, and a large number of polynuclear cells. The spleen was much altered; the lymphatic follicles had almost completely disappeared; the fibrous trabeculæ were thickened; in the pulp were lymphocytes, mononuclear and non-granular cells, polynuclear cells, myelocytes, and a few nucleated red corpuscles. In the bone marrow were giant cells in a state of activity, various forms of myelocytes, among which were many basophiles and eosinophiles, and some nucleated red corpuscles. The mesenteric glands were almost entirely transformed into myeloid tissue. Clinically two periods can be distinguished in this case of leukæmia which proved fatal in eight months. At the beginning gastro-intestinal symptoms, severe abdominal pain, and repeated vomiting were dominant; then the general health failed and ascites developed. When after paracentesis the masses were felt in the abdomen both the history and the signs seemed to render the diagnosis of tuberculous peritonitis probable. The condition of the spleen was typical of myelogenous leukæmia but this was not the case with the intestinal lesions. The whole of the small intestine was thickened by the formation of a new coat which in places formed small bosses and in others veritable tumours (myelomata). The clinical importance of the intestinal symptoms in myelogenous leukæmia has been pointed out by Rendu and by Jossuet. But no case appears to have been recorded in which abdominal masses were felt during life. M. Letulle and M. Halbron conclude that both clinically and anatomically the evidence shows that an intestinal form of myelogenous leukæmia may be distinguished.

AN ANNOTATION BY JOHN HUNTER.

MARGINALIA by famous men have always an interest for intelligent readers, even when their writers have apparently been actuated by a fit of temper or even fury. John Hunter was a good hater who often nursed a grievance and he was wont to scourge his adversaries and those who had offended him with no mean vigour when occasion offered. Thus we find him scribbling on the margin of one of the original manuscript Hunterian Museum catalogues sentences which even after the lapse of more than a century retain all their pristine acrimony. The writer of the catalogue is speaking, in a note or appendix, of the famous dispute on the absorbent nature of the lymphatics. "In the Life of Dr. Hunter," he says, "written by Dr. Simmons [John Foart Simmons] we find a desire of robbing him of the discovery of the lymphatics being absorbents, and to prove that he was not the discoverer a passage is quoted from Noguez' works." The mention of this writer provokes John Hunter to the following characteristic outburst. It was scribbled, apparently in great haste, on a stray scrap of paper and has been bound into the catalogue and piously furnished with a transcript in full by Hunter's disciple, the College Conservator, William Clift. "Noguez' work," says John Hunter, "is what they call an improvement upon Keil, but I may venture to say that those who are only able to publish the works of others are themselves not fit to publish any thing in that way; for they can never be a judge of what should be added, nor what should be taken away; for if they were perfectly master of the subject, then they certainly could make a better book themselves upon the subject. It is much easier for a man of real knowledge to make a new work than to mend an old one. It is clear that they can only in real knowledge be cobblers; and indeed there are few works that deserve a new edition, when they require additions, excepting by their original author." There is much to commend Hunter's view.

THE TRAINING OF WORKHOUSE INFIRMARY NURSES IN YORKSHIRE.

THOSE who have watched the development of the art of nursing during the last quarter of a century, and who must of necessity have been struck by the improvement that has taken place in the attainments of nurses in the various hospitals throughout the kingdom, cannot have failed also to note the desire on the part of the public to be supplied with properly trained nurses in cases of illness and the gradual improvement in the status and training of nurses in workhouses and union infirmaries. Some time ago a conference took place between certain of the unions of the West Riding of Yorkshire with the idea of arranging some scheme of training and of examination on a common basis, but no definite conclusions were arrived at. During the last ten years the guardians of the Leeds union have provided a systematic course of training for probationer nurses and the results have been eminently satisfactory. The union infirmary, which is undergoing substantial reconstruction and will be considerably enlarged, is certified at present for 650 cases, exclusive of 120 imbeciles. The number of acute cases and of surgical cases is considerable. During the year 1904 there were 2474 patients admitted. In such an institution which has as its head an experienced resident medical superintendent in the person of Dr. J. Allan, who is assisted by two juniors, the training can, as might be expected, be thorough and efficient, though even in this case it would be desirable if an arrangement could be made for the nurses, during some time of their training, to spend some months at a large general hospital to extend their surgical training. The staff consists of a matron at a salary of £100, an assistant matron, a sister whose duties are mainly in the nursing home, a night superintendent, and ward sisters at salaries of from £32 to £35, together with assistant nurses and probationers who are undergoing a course of training. These constitute in all a staff of 60, exclusive of those in charge of the imbecile department. The probationers attend on two months' trial. If found suitable physically and it is thought that they will turn out good nurses they then "sign on" for three years' training and during this time they are paid at the rates of £10, £14, and £18. They are instructed in systematic classes and tutorial classes first by the matron and then by the resident medical superintendent. At the end of their three years' training they are examined by an independent external examiner by means of a written examination and by a thorough *vivâ voce* examination, and on his report, coupled with that of the resident medical superintendent and the matron, the certificate of efficiency is given or withheld. Since 1895 about 100 nurses have obtained certificates and the examiner has had no difficulty in the maintenance of a satisfactory standard. During the last few years the guardians of the Hunslet union have instituted a course of training on much the same lines as those above noted. Mr. J. Buck, the visiting medical officer, worked for some years under Dr. Allan and has taken up the work of lecturing to the nurses and instructing them in tutorial classes. The handsome and beautifully equipped workhouse and infirmary of the various parishes within this union, which represent a population of about 83,000, were opened some 18 months ago. The present accommodation is for 450 but the administrative block is adapted for double that number and the site covers an area of 18½ acres. The infirmary is a separate building, connected with the main building by a covered corridor, and consists of a central block which includes the nurses' quarters and of pavilions for males and females, which together give accommodation for 146 patients. There are also a small maternity block for five cases and a separate block for imbeciles with accommodation for 36. The staff consists of a matron at a salary of £45, three charge nurses, and at present eight probationers. The charge nurses are paid £30 and the probationers at the rates of £12, £16, and £20 for their three years of training. At both institutions the accommodation for the nurses is excellent; good bedrooms, sitting rooms, and recreation rooms are provided, and the guardians have shown themselves willing to fall in with any suggestions from the medical officers and from the external examiner who is the same for each union.

SLEEP IN CASES OF CEREBRAL TUMOUR.
